BARR-HOLADAY LUMBER CO.

BAND MILL AT LOUISE, MISS. **GREENFIELD, OHIO**

It Stands Out Above the Average

The general consensus of opinion is that Iowa-grown Walnut possesses a shade better grain and marking on the average than other Walnuts.

Selected Iowa-grown logs, cut with extreme care to preserve the inherent beauty make IOWA WALNUT. You owe it to yourself to investigate before you buy. Write or wire to-day for quotations.

MAHOGANY

Rarely are such stores of precious wood to be found as may be seen in our yards. Across the seas from tropic lands it comes. From thick jungles where the light of day but dimly penetrates and where tangled native paths make difficult the bringing out of timber. Here the black man labors, risking life from jungle dangers, that supplies will not diminish and your orders may be filled.

Twelve million feet per year is the capacity of OTIS mills. An adequate supply is always on hand for prompt shipment. Get our prices.

THREE GUESSES

Electric power, heating, lighting and equipment problems are to be found in the lumbering and woodworking industries.

Perhaps your output can be increased? You are, perhaps, losing electrical energy by wasteful types of motors? Are your switches and wiring devices up-to-date or are you in continual danger of fire?

We shall be pleased to answer any questions or help you with any problems whenever you care to write us.

Oak Red Gum

Why Bruce Hardwoods Excel

For many years before we became hardwood lumber manufacturers, we were makers of fine Oak Flooring and are to-day the largest individual producers of that material.

The producing of good Oak Flooring is an exacting science—where perfection is attained—and teaches the value of both skilful grading of raw material and accuracy in milling.

With a full appreciation of the value of these factors, we entered also upon the manufacture of southern hardwoods and in the operation of this department, have applied them in the production of all items in white and red oak, gum, ash and other species.

With our joint facilities, we are equipped to ship square edge parquetry strips, oak trim and mouldings, as well as Oak Flooring in the same car with hardwood lumber.

Inquiry and correspondence invited.

Is Price-Cutting Justifiable?

Such articles as "Is it Profitable to Sell at a Loss?" and "The Facts Behind the Cost Figures," which have appeared in recent issues of the "Canadian Woodworker and Furniture Manufacturer," have been read, judging from comment made, with a considerable amount of interest. While not advocating price-cutting in any shape or form when the sole object is to secure business in the face of keen competition or to undersell the other fellow at any cost and show him that others can cut as low as he can, there are times when it is not only reasonable and commendable to sell at or even below cost but when it is absolutely necessary to do so in order to secure a sufficient volume of work to hold an organization together, reduce overhead and in various ways lessen what would otherwise be a larger loss. This is the situation in some woodworking plants to-day.

In the furniture field the manufacturers of certain lines of furniture are none to busy. The same may be said of the operators of general woodworking plants catering particularly to special order work. The activity in the residential building field has resulted in a strong demand for various kinds of stock millwork, but very few builders, either private or speculative, are showing any desire to pay for special work. This means that certain furniture manufacturers and certain other woodworkers are finding it decidedly quiet at the present time. What can they do to stimulate sales or to prevent serious losses being incurred?

It has often been intimated that as a rule woodworkers are inclined to substitute price-cutting for salesmanship. There are many things a manufacturer can and should do to stimulate sales before he resorts to the blue pencil, but, on the other hand it cannot be denied that price is a factor to be reckoned with. Almost anything can be sold at any time provided the price is made sufficiently attractive. If it is considered advisable to make any reductions they should be made on an intelligent basis, that is, with a full knowledge of costs and all cost factors, and with a definite object in view.

One woodworking concern has adopted a plan along the idea outlined in the article in the April "Canadian Woodworker" entitled "Is it Profitable to Sell at a Loss?" By taking the orders on file and checking them with cost data covering similar work, the number of hours of work ahead of each department was ascertained. This information was put in chart form and the chart kept up to date. If, for instance, the chart shows that the door department has not sufficient work ahead, a determined effort is then made to land some orders. If inquiries for doors are received the prices are made unusually attractive, and, in addition, contractors and others putting up buildings, are interviewed and a strong effort made to land the door business, at least. The same procedure is followed when other departments are faced with a slack period. Working ahead in this manner, it is necessary to wait until a department becomes slack before work is sought, but as soon as the chart indicates that any department is rapidly cleaning up the work on order, steps are taken to secure more work for such departments. The intensity of the effort and the price concessions made are determined entirely by the urgency of the situation as indicated by the chart.

Back of all this there should be a persistent, determined effort to bring down the cost of all work to as low a point as possible. Waste, that is waste material, waste labor and misdirected effort should be sought out and eliminated. Various lines of new equipment should be investigated, and if a saving can be made with a new machine, there should be no hesitancy about purchasing it, as it will quickly pay for itself. New methods and new ideas should also be carefully analyzed with particular reference to their application to your requirements. In this connection the industrial engineer is beginning to play an increasingly important part in the woodworking field. Through the aid of industrial engineers costs are being reduced and the productiveness of workmen and departments increased. One large Canadian manufacturer, producing a varied line of furniture, recently engaged the services of an industrial engineering organization which specializes in the woodworking field. The cost records of this concern show that as a result of the work done, the costs of certain sticker operations were reduced 59%, 43% and 34% respectively and other important savings effected. This is merely a suggestion of what can be accomplished if gone about in the proper manner.

Will Radio Craze Affect Phonograph Sales?

Drop in Phonograph Sales has Alarmed Many—Will This New Competition Assume Formidable Proportions?—What Past Experience has Demonstrated

In the phonograph field both the manufacturer and retailer are wondering just what affect the widespread interest which is being evinced in wireless receiving sets will have on their particular business. Is this to be considered a competitive line? Will the strong consumer demand for wireless sets result in a decreased sale of phonographs? The question is an interesting one, especially so as there is something to be said on both sides.

There is little doubt that in the first enthusiastic rush for wireless receiving apparatus, the phonograph industry will suffer. The attention of many people will be centered on wireless rather than on phonographs, with the result that record sales and exchange sales will show a decline. Further it is only to be expected that some who were on the verge of investing in a phonograph, will defer the purchase of that instrument in favor of a wireless set. This is only natural, for people are being carried away by their enthusiasm for this new and wonderful instrument, but this is only an initial and passing phase.

Advantages with Phonograph

The real test will come when the first enthusiastic rush for that which is undoubtedly novel and interesting is over, and the public have had a chance to allow their reason and judgment to come into play. At first thought it is nice to be able to "tune in" on the air and catch distant concerts and music of various kinds. The first time I "listened in" I experienced a distinct thrill. The idea of picking up music out of the air was almost unbelievable. After the first few evenings, however, the drawbacks and annoyances of this form of home entertainment gradually became apparent. First and foremost it is out of the question to select and choose; one has to be content to take what comes over or switch off. Again, the receiving apparatus may not be working properly or there may be a lot of "interference" in the air, with the result that the music is weak and indistinct. Another drawback, and a real one, is that we cannot "tune in" at any minute of the day or night and pick up something good.

For these reasons alone it is not unreasonable to suppose that the phonograph will be able to continue to hold its own. One can start this instrument at any time one wishes. There is an almost unlimited range of records, covering music in all its forms, from which to select, and favored selections may be repeated time and time again. There is another phase, however, which will tend to maintain the popularity of the phonograph in the face of any kind of competition, and that is the permanency of the records and of the master records from which the composition records are reproduced. Caruso can never be heard over the wireless, but with the phonograph one can hear him at leisure. The same holds true of other departed stars. In this particular direction the phonograph is supreme.

Taking Counsel from the Past

Some years ago, and not so many at that, when the demand for phonographs was increasing by leaps and bounds, the makers of pianos began to feel alarmed, but, upon second thoughts and a closer analysis of the situation, they realized that anything which tended to educate the public to music or that tended to increase the popularity of music, could not help but result in an increased demand for pianos. Time has proved the correctness of this conclusion for in spite of the fact that phonographs have been sold by the hundreds of thousands, the production of pianos has been increased and a ready market found for all that have been made. The same will undoubtedly hold true of wireless. If it tends to arouse a greater interest in music, it will, probably, result in an increased sale for both phonographs and pianos.

This is the attitude taken by Ralph Freeman of the Victor Talking Machine Co., who said recently,—"The radio broadcasting of music is a useful and a very wonderful thing and it is working for us all the time—by creating a love for music. There is a mistaken idea that the radiophone is a competitor of musical instruments. It is not so. Rather does it go hand in hand with our business. There are wonderful possibilities in the radiophone field but it will not break into that of musical instruments."

To Promote "Furniture Weeks"

At a meeting of the directors of the Home Furnishings Bureau held in Toronto recently, it was decided to make a small assessment on the members for the purpose of promoting a number of special furniture weeks in various centres. A general meeting of the Bureau is scheduled for Wednesday June 14th when plans for the next twelve months will be formulated.

A detailed outline of the results of the special Furniture Week held recently at Windsor, Ont., was presented by Mr. Blogg, who pointed out that the furniture made by the members of the Bureau was featured all during the week, with the result that the membership secured some good business. Those present stated that they had received many nice orders as a result of this "furniture week," and considered that a series of displays of this kind during the fall months would act as a stimulant on the fall trade.

A vast amount of good can be accomplished at a comparatively small outlay through the promotion of special weeks of this kind and in other ways bringing furniture prominently before the buying public. As a whole the furniture industry stands to benefit from the activities of the Bureau, this work should receive the support of the industry as a unit instead of a limited number of furniture manufacturers standing all the expense as at present.

The American Homes Bureau are endeavoring to promote a National Furniture Week some time in October. The scheme is to have furniture featured in every city, town and hamlet in every state of the Union. There is no doubt that if this idea can be put across it would result in arousing a greater amount of interest in furniture and the furnishing of the home. This national scheme presents a goal at which the Home Furnishings Bureau of the Canadian Manufacturers might well aim.

Making Furniture on Gravity Conveyors

How a Progressive Manufacturer Has Organized His Plant—Handling Costs Reduced with Gravity Conveyors — Work Thoroughly Systematized—Eliminating Confusion and Costly Delays

Multiple production! The term is familiar to everybody, yet it only became prominent in the English language a few years ago. Perhaps it was born when Henry Ford applied the rule of multiplication to those fast little "Lizzies" that dot the globe in every clime. Perhaps the date was earlier, but, anyway, we have with us today, "Multiple Production," and it is going to stay with us for a long, long time.

That little manufacturer, with the big vision and the yearning look—ask him what he is longing for, and he will answer, "Multiple Production." That big fellow, whose plant covers acres and whose checkbook is bigger still—let him whisper in your ear the cause of all his prosperity, and don't be surprised when he tells you, "Multiple Production."

It is in the air. It has invaded and pervaded every industry, and the aromatic red cedar chests that are useful as well as ornamental adjuncts of our homes are now the result of multiple production.

Planned for a Purpose

A salient example is found in the plant of the Standard Red Cedar Chest Company located at Altavista, Va. It is a new factory, not yet a year old, and it was planned with (and for) a purpose. The builders did not simply erect a structure and then occupy it. They first gave careful thought to the character of the work to be produced and how it could be produced most advantageously, and with this as a basis the factory was consummated. In other words, they laid out their processes and then erected a building around them.

It is interesting to witness the real science of production, the science that obtains lower manufacturing costs, a better product, maximum production in minimum space, and an extraordinarily satisfactory service to customers.

In the Altavista plant the lumber is first sawed and then scientifically treated in dry kilns. Perhaps the term "drying" is anomalous, for it is the mission of the kiln to provide sufficient moisture to prevent the boards from cracking, and to retain the proper amount of oil in the lumber to supply the odor necessary for moth prevention. So, you see, a dry kiln is not wholly a dry kiln; it is an institution that scientifically treats woods.

Conveyor Belts Take Hold

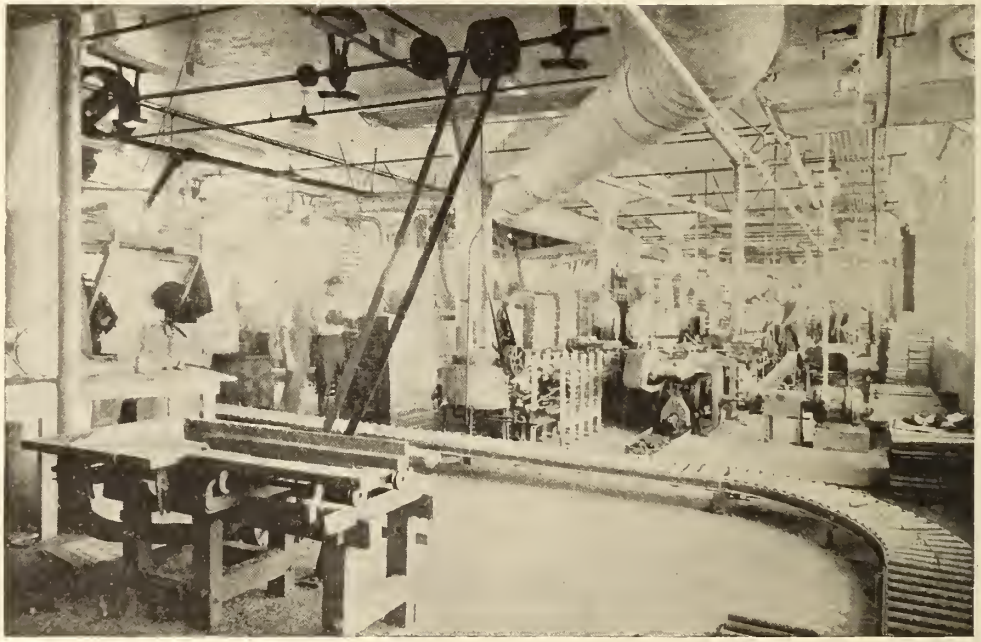
From the kiln the lumber is delivered to the machine department, where it is cut to the necessary lengths and freed from all defects. It falls on a belt conveyor that at this particular juncture moves toward the grading department where skilled "pickers" sort out the panels, selecting those that can be used to the best advantage.

And then another machine comes into action. Machines and more machines till the last step is reached, because it is not expedient, according to multiple production, for any man to do what a machine can do.

From the time the red cedar lumber enters the door until the finished chest is delivered to the packing room, machines are glutted with work, via the belt conveyor. No trucks are used for handling the panels.

Well, from the grading department the panels roll through the dove-tail glue jointer, which makes a joint that is stronger than the natural wood itself, as proved by tests. Onward they go to be dressed, sanded and trimmed, and the tenoner gives them a sharp welcome and a cutting goodbye. It is the tenoner that makes the famous double-lock corner which

Conveyor trucks and racks are employed in the finishing room to handle the work.



View in machine department showing line of gravity conveyors

The chests are assembled on conveyors, and as in the Ford plant each man performs certain operations as the boxes move along.

enables the workmen to assemble sides and ends without nails or screws, obtaining a joint that is air-tight and dust-proof.

The mention of workmen in the last sentence is really an error, for the sides and ends are assembled by machinery. Apparently the workmen just look on and collect their pay checks every week, but as a matter of fact the assembling machine does a better job than human hands could ever accomplish. The joint is tighter and when the bottoms are put on in the same way, the tiniest particle of dust or the most persistent moth could never find a crevice for entrance.

What was formerly lumber and panels now begin to look like chests, and they slide down a gravity conveyor by the sides of which men are stationed at intervals. Each man does his particular piece of work on the chest with speed and precision, and he is a specialist at his task, constant and intensive application to one line of labor giving him the highest skill possible. In this way the maximum amount of production is obtained with a minimum amount of effort.

All operations in the Standard plant are tested by that increasingly popular invention, the time-study watch. This instrument gives the duration of any process to the fraction of a second, and permits the manufacturers to determine the best and speediest method of doing the work, for multiple production demands speed.

Conveyor Trucks in Finishing Room

In the finishing department the chests are handled on skids with lift trucks, and by this method more speed is obtained because ten or a dozen chests can be manipulated where only one could possibly be handled in the old way.

The varnish is applied by spraying systems which give a better and more uniform finish, and this finish is rendered a high degree of permanent beauty by means of a specially constructed kiln which dries the varnish scientifically.

Now the chest is finished, and it goes to the packing department. Here, too, the ever-present conveyor is a willing server, carrying the work to the men who, like in the cabinet department, stand at the sides and perform their particular tasks speedily. Throughout the plant everything is moved by belt conveyor, gravity conveyor or lift trucks—nothing is allowed to touch the floor or to stop. The path is laid out for the material and it has to keep moving quickly. Even when the chest is packed and crated a gravity conveyor delivers it to a tram car which carries it to the warehouse.

Every Assistance to Dealers

Such, in brief, is the story of multiple production in a plant making cedar chests. Every operation, from cutting the standing trees of red cedar to the delivery of the finished product, is controlled by the manufacturers, and the machinery is of the highest type, insuring the best quality of workmanship at the lowest cost.

But the service rendered to retail dealers does not end there. Multiple production is naturally dependent upon distribution. Things that are made must be sold or the factory chokes itself with surplus stock, and so the manufacturers provide the dealers with efficient sales helps, such as electrotypes and matrices for newspaper advertisements, and for window displays attractively colored show-cards, cedar-logs, shavings and other stage accessories that will aid in making an eye-compelling window.

Thus every step of the way—from the cedar groves to MiLady's boudoir—the keen insight and foresight of multiple production is obvious.—"Furniture Index."

Bending Southern Oak Chair Posts in Hot-Plate Bender

Effect of Length of Steaming Period—Tension Failures and Their Prevention—Summary of Studies Made

By W. K. Loughborough

(Continued from May issue)

There seems to be a definite relationship between the length of the steaming period and the amount of surface checking resulting from the bending process. This is because the steaming alters the moisture content. If stock contains little moisture, invariably more surface checks follow the longer steaming periods than the shorter ones. If the fibers are saturated with moisture, varying steaming periods have no effect upon surface checking. In order that surface checks may be prevented, the steaming period should be no longer than is necessary to produce the required degree of plasticity.

The proportion of rejections from surface checking becomes greater with an increase in the moisture content and in the severity of the drying conditions, that is, the steam pressure used in the bending plates. Bending and drying material that contain 40 per cent of moisture between plates heated by 55 pounds of steam pressure is sure to result in a total loss.

There is a decided tendency for the stock that has a high moisture content to fail in tension with the longer steaming periods. As the tension failures start in the plane of medullary rays, which is also the plane of surface checking, an increasing tendency of the stock to surface check when the quarter-sawed faces come in contact with hot plates will produce an apparent increase in the number of pieces that fail in tension. A surface check on the side (and near the lower side) of the post usually passes through the surface brought in tension. If the tension stress of bending is added to planes already weakened by shrinkage stress, the chances that the stock will fail in tension are increased in proportion to the increase in the tendency of the stock to shrink.

As would be expected, surface checking in chair

*Assistant Engineer, Forest Products Laboratory Maidson, Wis.

posts increases as the temperature between the plates increases. Generally speaking, the steam pressure in the hot-plate benders should be as low as the production requirements will permit. It should never exceed 20 pounds. Other conditions being the same, there appears to be no marked difference in the number of rejections for any cause whether 5 or 20 pounds of steam is carried in the plates. However, a pressure of 55 pounds results in a large loss upon surface checking even if the moisture content of the stock does not exceed 15 per cent.

It is the custom to bend chair parts so that the quarter sawed surfaces will be in the positions of the most prominence in the finished product. Usually, as with an oak back post, the figured surface is brought in contact with the hot bending plate. If for any reason it is bent the other way, that is, with the tangential face up, the surface of the material checks much worse than if it is bent in the usual way. Compression failures also are more common in bending oak posts if their tangential surfaces are brought in contact with the hot plates than if their radial surfaces receive the maximum heat.

Trouble from Compression Failure

This increase in compression failures seems to occur as the result of an increased amount of surface checking. It is evident that in the southern oak the plane of the medullary ray is weak; whatever failure occurs during the bending and drying processes occurs in that plane. The tangential face surface checks in the plane of the rays as the wood dries. It appears that the surface tension, due to drying in the hot plate bender, in conjunction with the stress due to bending, must strain the medullary ray to the point of rupture, thus producing lateral folds. This rupture of the lateral folds would appear as compression failure if the material were deformed by a stress applied at right angles to the annual rings. If the rupture occurs in material deformed by a force acting in the direction of the tangent of the annual rings, it may appear as tension failure, as already mentioned. It seems to be quite evident that the surface tension caused by drying does increase the stresses. If the tangential surfaces are placed in contact with the hot plate, the maximum surface tension is obtained. The three factors influencing surface checking are brought into action at once; a rapidly drying surface having the largest shrinkage potential is subjected to the most severe drying conditions.

If quarter-sawed material is bent with the quarter-sawed face in contact with the plates, the reverse is true; the drying conditions surrounding the tangential face are much milder, because the temperature is cooler; and, as no opening is left between the pieces, the humidity tends to become higher. It seems that the pieces whose annual rings cross the cross section diagonally dry with the least surface checking, and, in fact, make the best looking posts, as all four surfaces show a good figure. The natural tendency of such posts to diamond is prevented by the plates.

Preventing Tension Failures

Although wood fibers can be squeezed together more than the ordinary chair post bend demands without damaging results, the amount of stretch which wood will endure is very limited. It is important to prevent tension stress as much as possible. It was found that loss from tension failures can be controlled and practically prevented by applying before and maintaining during the bending processes sufficient compression on the ends of the pieces to prevent the convex surfaces from becoming stretched. The factor of end pressure is probably the biggest factor influencing tension failures. Within practical limits, the losses from tension failure were inversely as the pressure applied. This was true regardless of any other factor.

Because of the importance of compression stress parallel to grain it is evident that all posts in any one plate should be exactly the same length, for this makes it possible to apply the proper stress to each post. In general, the best results are obtained when enough pressure is applied to put a slight reverse camber into the post before bending. It is important that the pressure be distributed evenly over the entire end surfaces of the post; otherwise there is a decided tendency to shear at the ends. A simple way of obtaining an adequate amount of pressure is to drive wedges between the iron tenplates riveted onto the straps which hold the material and a strip of stout material placed at the ends of the post.

The time for the tests was so brief that it was necessary to limit the study to one class of material—white and red southern oak—and to one form of bend. By watching the operations in the bending room an idea was obtained of how other woods and forms bend. Rock elm gives the least trouble under the most severe bends. Mahogany, birch, and gum have a tendency to fail in compression in the order given. None of the ring porous woods seemed to fail in compression if they were bent with the radial surface against the plates. Even the walnut post did no fail in compression. Gum warped more than the other woods in the plate bender; but this trouble was overcome by wedging in the strap against lateral deflection before the plates were closed. All species seemed to surface check somewhat, but oak checked the worst. So far as noted, maple seemed to surface check the least. Tension failures did not seem to be more prevalent in one species than in another. However, it was impossible to isolate the factor of species to determine this point absolutely.

Bending Characteristics of Different Species

In bending the quarter sawed oak pieces about 1 inch thick and from 5 to 8 inches wide, it was noted that compression as well as tension failures occurred. The compression failure produces a wash board appearance across the surface. These failures were not noted in the bending of the narrower oak parts, such as rockers and chair posts, even though the amount of deformation was practically the same. Superficial observations indicate that compression failures occur in the plane of the medullary rays, regardless of the way the oak is turned in the plates. It also seems evident that the tensile strength of the fibers across the pain is a constant factor, but that the stress required to deform wood varies directly as the width. Consequently the wider or deeper the piece bent the more chance there is for failure in compression. It seems impossible to apply the end pressure so as to distribute the stress evenly. Consequently the wood fails at the weakest first, then gradually clear across the width of the piece.

Summary of Conclusions

1. If 1 by 2 inch southern oak chair posts are to be bent in a hot plate bender, the center of the stock

(Continued on page 94)

Grinding and Jointing Planer Knives

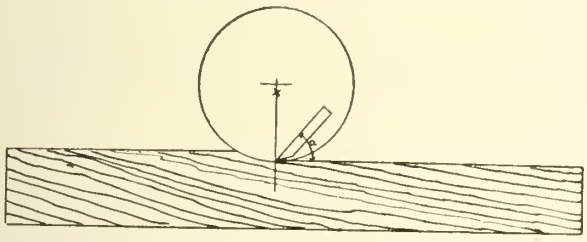
Time and Steel Both Conserved by Grinding on Head—Proper Cutting Angle and Heel Clearance—Jointing Brings all Knives into Cutting Circle Though This May be Accomplished by Grinding Knives on Head

By A. P. Redden*

There is room for considerable improvement in the knife grinding and jointing methods as followed in many plants. The old laborious and inaccurate method of removing the knives from the heads, grinding them and then tediously setting them in line with the bed is rapidly passing into disfavor and is being replaced by modern grinding-on-head and jointing practices.

The angle or bevel on the knife itself is of prime importance and often makes the difference between poor and satisfactory work. The accompanying sketch shows the usual method of measuring the knife angle. "X" is a perpendicular passing through the centre of the cylinder, "A" is the angle of cut. The edge of the knife coincides with the points of intersection of the perpendicular and the stock.

The proper angle of cut depends upon the kind of stock being planed, also the quality and quantity of work required. Softwood and quick work from



Showing how angle of cut is ascertained

38 to 45 degrees. Hardwood and fine work from 80 to 85 degrees. This will not rip any cross grained stock. An angle of 65 to 70 degrees has been found to give the best universal results. The different angles of cut are generally obtained by back grinding, however the manufacturers of cylindrical heads are making heads with the knives set at a greater angle than formerly and back grinding is not necessary.

Proper Bevel for Planer Knives

The amount of heel clearance used is something that is generally carried to excess. The heel of the knife should have a very small clearance. If knives are ground with a long bevel, the edges will be thin and weak, very easily nicked and will also chatter in the cut, and if set with a short overhang are sure to crack.

Many planer men drift into the habit of long bevels to avoid grinding. Taking off, grinding and resetting knives requires a lot of time, and if they can whet and file them a couple of times more think they are saving time. This is a mistaken idea, the thin edge will not stand up and knives and time are both wasted.

The advent of electricity into the factory and mill has brought many valuable devices, including motor grinding devices for grinding the knives in their place. This is fast becoming a universal practice. With this method the knives can be ground with just the proper clearance, and when dull can be reground in less time than is usually spent in whetting. Knives should never be ground with the periphery of a small wheel, this makes the edge too thin when the heel clearance is right.

Why Knives Should be Ground on Head

It has been proven beyond a doubt that knives ground in place will last three times as long as those taken off for grinding. In the Weber Piano Factory, Worcester, Mass., a set of high speed steel knives lasted three years by this method whereas a set taken off for grinding, (doing the same work lasted less than one year.

Every time a knife is bolted onto a grinding machine the knife is sprung by the drag of the bolts, and when reset on the head the same thing takes place. Grinding in place is acknowledged by nearly all to be the proper method. The qualifications for a grinder should be:

First—Easily transported from one machine to another.

Second—Quickly set up and taken down.

Third—Grind a nearly flat surface, just slightly concaved, giving a strong edge.

Fourth—Grind each knife on the same head the same length and grind true to the bed without adjustment each time.

Fifth—Grind quickly and without burning the edge of the knife, this can be accomplished only by a certain pressure on the wheel which has been pre-determined and cannot be changed.

Hints on Jointing Cutter Knives

Jointing knives while the head is in motion is quite widely practiced. A head running at high speed has a throw caused by imperfect balancing It may be in perfect standing balance, yet be out a lot when running. A jointer corrects this but when the cutters have been jointed they should be ground to an edge before using, Of course, this must be done with the knives in place.

Many large manufacturers of pianos and furniture have found by grinding the knives on the head, jointing is not necessary. The jointer may be used largely with the old method of grinding, but is used now only where the finest mircrometer planing is necessary or the improved methods of grinding have not been adopted. The real reason for jointing is to have every knife doing its share of the cutting. If this can be accomplished by grinding on the head and it can if the knives are ground so as to leave a silver edge or in other words a slight streak of bright metal showing, there is nothing to be gained by jointing.

Boring 7,200 Holes an Hour

How Savings are Being Effected with Multiple Spindle Boring and Mortising Equipment—Machines Pay for Themselves in Quick Order—Experience of an American Furniture Manufacturer

In the production of furniture and other forms of woodwork the boring of holes and the making of mortises are two important operations. In the past this work has been done largely on single spindle machines, but in response to the demand for more efficient methods and for ways and means of reducing costs, the manufacturers of boring and mortising equipment have developed multiple spindle machines which not only enable more work to be put through in a given time, but the work is done with a degree of accuracy not usually encountered with single spindle equipment.

From actual experience it has been found that where any considerable volume of production is handled, multiple spindle machines are able to show a marked economy in the saving of time required for the boring and mortising operations. A further saving is also made in the assembling operations where special fitting is often required because of inaccuracies in the boring or mortising. A gang machine when set up for any particular job will turn out parts which correspond in every way, regardless of the number put through and so has an important bearing on assembling costs.

Handling Time the Same

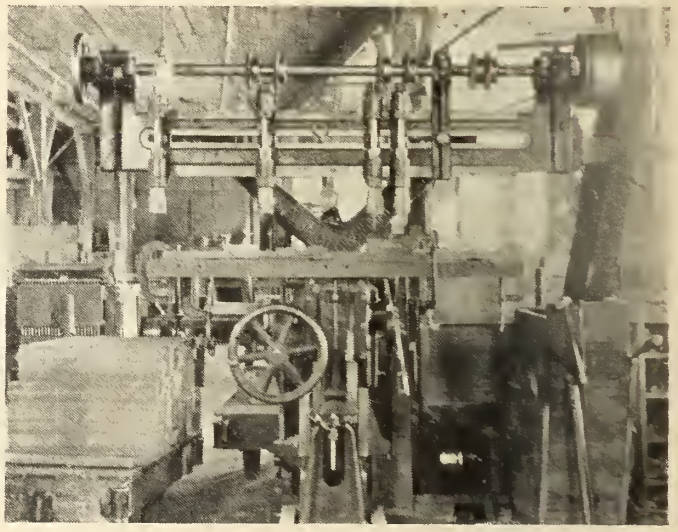
The handling time required to place a piece on the table of a single or multiple spindle machine is the same, and as much time is required to bore one hole on a single spindle machine as to bore from two to twenty holes on a multiple spindle borer. With the single spindle machine when a number of holes of the same size are to be made in a piece, an elaborate set of stops must be provided to locate the material in the different positions so that the holes come in the right places, and in the event that the holes are staggered, this stop system is still further complicated. In many types of gang boring machines the spindles may be so spread and adjusted that the holes can be bored over a wide area either in straight lines or in irregular positions without in any way affecting the handling or retarding the production of the machine. Another point to consider is that where various sized holes are to be bored in the same piece, the proper sizes of bits can be placed in the different spindles of the gang-boring machine, and all the holes made at once, whereas with a single borer only one sized hole can be bored in a piece at one handling unless the machine is stopped and the bit changed.

Rates of Feed Carried

The two types of machines usually differ with regard to the feed. This is particularly true of boring equipment. With the single spindle borer the bit is usually fed into the wood either by hand or with the aid of a foot lever. In either case the operator does not have free movement for quick action in handling the material. On the other hand with the multiple spindle machine the output is limited only by the speed at which the man can get the pieces to the machine and away from it between the boring strokes which are automatic.

The rate of feed usually carried on the modern multiple spindle machine usually runs from 10 to 22 strokes a minute, depending particularly on the size and shape of the piece handled as this affects the speed with which the operator may pick up and lay down the stock.. In any event the rate should be so set that the machine will set the pace for the operator and so that he will have to devote close attention to his work to keep up with the machine. On very light work faster feeding rates are possible in some cases running as high as from 35 to 40 strokes a minute with one piece being bored at each stroke. However, these latter rates of feed are the exceptions rather than the rule, but from 15 to 20 pieces per minute can be considered as a fair average speed.

In furniture work the multiple spindle boring machine is usually made to bore in one direction although there is a tendency toward equipment which will bore in two or more directions at the same time. Boring machines are also available which will bore both straight and angle holes in the same general direction. In this connection it might not be out of place to mention that small cluster spindle heads are often used for boring groups of holes with close centres. These can be used on either single or multiple spindle machines, but where there are a number of groups of holes to handle, the multiple spindle equipment is to be preferred, for not only can the different groups be bored at the one operation, but the spacing between the groups is always accurate and uniform.



A Fay & Egan multiple spindle boring machine in plant of the Office Specialty Mfg. Co., Limited, Newmarket, Ont.

While it is out of the question to lay down any hard and fast rules as the conditions under which the boring is done in each plant varies, it may be taken as a basis for analysis that any plant handling any volume of work in which two or more holes appear in the same piece can profitably use multiple boring equipment. Even in some of the simpler forms of work

requiring only two or three holes, a machine of this kind often saves its full cost the first year.

Pays for Itself Quickly

An instance of this kind is the case of a woodworking concern which spent $1,300.00 for a multiple spindle borer and found that it paid for itself seven times over during the first year. Another instance of this kind is where a manufacturer had a large boring job, 55,000 pieces, and figured that the multiple spindle machine he installed to handle this work saved its cost five times over on this one job alone.

Multiple spindle mortising does not present equal possibilities in cost reduction and increased production as multiple spindle boring machines although when mortise and tenon construction is used on designs where several mortises of equal length appear on the same face of the stock, the multiple spindle mortiser can be used economically and with the same advantage as the gang boring machine, both with regard to time saved in the handling of work to the production of the machine and to the perfect duplication of the work. Where the length of mortise does not exceed the width by more than 50 per cent. it is possible to use an oblong chisel and complete the mortise in one stroke. For mortises of greater length as compared with the width, it is necessary to form them by making repeated strokes and moving the work along between each downward movement of the chisels.

Experience of One Manufacturer

The Furnas Office Furniture Co. of Indianapolis, Ind., who are using both multiple spindle boring and mortising equipment, have found this idea to be a money-saver. They have this to say,—"It would appear as if each manufacturer of woodwork can figure out for himself as to whether or not the multiple spindle idea can be used on his work. It is a very simple matter to decide. First figure the actual labor cost of running the entire job on the basis of boring or mortising one hole at a time, then figure the actual labor cost on the entire job by using multiple spindle mortiser or boring machine and making as many holes as possible at one time. If the difference in cost is large enough to pay the purchase price of a multiple spindle machine and, in addition, effect a substantial saving, obviously it is the part of wisdom to buy such a machine. Whenever possible it seems better to use a power feed machine having a known rate of feed so that it is easy to estimate how many pieces per hour the operator should handle on the machine. This, we find, gives a very accurate cost and a piece-work rate can readily be set on the operation and low productive costs be obtained.

"In our plant we find that where with single spindle machines we were formerly able to handle only 200 pieces per hour and make one hole in each piece, we are now able to bore 750 pieces per hour and from one to ten holes in each piece. The same holds true in the mortising for where we formerly put through 100 pieces per hour with one hole in each piece, we are now turning out 300 pieces per hour with five holes in each. The effect on cost and production is obvious. There is no doubt but that the multiple spindle idea is entirely practical and unusually successful."

Woodworking Equipment Costs Too Much

Is the Investment in Equipment Higher in the Woodworking Field Than in the Metal Working Trade?—Comparative Figures Covering Small Plants—Productiveness of Machine and Quality of Output Chief Factors

"It costs so much to purchase new equipment" or "Woodworking machinery prices are far too high," are remarks that are heard in nearly every plant devoted to the remanufacture of wood. Woodworkers in general are firm in the belief that they are being asked far too much for any equipment they may happen to need or that the prices of such machines are away out of line. Whenever new equipment is mentioned or even thought of, the question of price seems to be the most important phase of the deal.

There must be some reason for this attitude. Woodworkers as a rule are broad-minded and are fully alive to the fact that they must pay for what they receive. What then is the basis for the idea that they are being overcharged for their machinery needs? It might come under any one of three headings, first, that the prices of woodworking machinery are higher than those being paid by other industries for their equipment, second, that prices today are away out of line with those which prevailed some years ago, this in spite of certain reductions which have occurred, and third, that the level of values which are found in the woodworking equipment field is too high in comparison to the general trend of machinery prices.

What A Comparison Shows

Let us consider for a moment the first suggestion, that the prices being asked for woodworking equipment are higher in comparison with other lines of machinery, or, to put it in another way, that it costs more today to equip a woodworking factory than, say a metalworking plant. Just to get a basis for comparison, some figures were secured, covering the average requirements of a small woodworking plant and a small industry devoted to metal work. The lists and prices are substantially as follows:—

Woodworking	
Swing Saw	$ 135.00
Variety Saw	240.00
Band Saw	300.00
12-inch Buzz	423.00
24-inch Planer	675.00
3 drum Sander 36"	2,385.00
Post Borer	76.00
2-spindle Shaper	600.00
Lathe	198.00
8-inch Sticker	1,332.00
Disk & Drum Sander	253.00
Belt Sander	495.00
	$7,112.00

Metal working	
Lathes, 16" x 6'	$1,050.00
Lathes 20" x 12'	1,663.00
"Gap 20" x 38" x 12'	2,021.00
Planer, 36" x 10'	4,073.00
Shaper 16" x 20"	1,050.00
Power Hack Saw	65.00
20 inch Drill	180.00
36" Sliding hd. Drill	1,150.00
Small miller	1,075.00
	$12,327.00

These figures would seem to indicate that the cost of woodworking equipment compares more favorably with that of metalworking tools. Not only is the value per piece much higher in the metal working trade, but the investment per productive mechanic is more than double, being $1,582 against $592 in the woodworking field. That the operator of a wood working plant or one about to invest in woodworking

equipment has all the better of any deal calling for new machines.

How About Quality?

Taking up the discussion under the second suggestion, namely that the prices being paid to-day are away out of line with those which prevailed some years ago, there is more fact than fiction in this suggestion. The cost of woodworking machines is undoubtedly considerably higher than it was years ago, and most of us are prone to look back and make comparisons. This may be the reason for the attitude which commonly prevails. There may be, however, some justification for the prices being asked to-day. The question of quality must be considered. The woodworking equipment being placed on the market to-day is a highly specialized line of machinery and is designed and manufactured with a degree of skill and accuracy and with a fidelity to detail that was unthought of years ago. This has been due partly to the demand for higher speeds and better work and also to a realization of the fact that the woodworking industry requires precision tools, the same as any other field. Raising the standard of the product in this way cannot but mean increased prices, for not only is more time required for each of the many operations performed in producing woodworking equipment, but a higher degree of skill on the part of the workmen is necessary, which means more highly-paid help.

The question of guards and protective devices of various kinds has not been without its influence. on certain machines the guards and safety devices alone account for a good 10% of the total cost or total price. This is a feature that did not enter at all some years ago, and is in reality a blessing in disguise for the safety devices found on modern equipment has annually saved the woodworking industry thousands of dollars in workmen's compensation dues and in claims for damages.

True Basis for Judging Value

The suggestion that the value of woodworking equipment is out of line with the general level of prices, does not hold. The comparison made between wood and metal-working equipment proves this. The manufacturers of woodworking machines claim that the prices prevailing some years ago were out of line, that they never represented a fair return on the cost of production, and as a result woodworkers have been educated to low prices and believe they are being over charged, when asked a price which offers a fair return on the true cost. Another point is that formerly much of this equipment was made under the apprenticeship system, with help that was fairly efficient and which was not paid very high wages. To-day none but skilled mechanics are available, for, as we all know, the apprenticeship system is a thing of the past. Anyway, as intimated before, more skill is required to-day in the production of modern woodworking tools. Taking it all in all, it does not appear as if the cost of woodworking equipment is out of proportion to the value given or that woodworkers are being asked to pay more in proportion than any other buyers of machinery of a similar quality.

The true basis upon which to judge the value of any machine is not the initial price but it is productiveness and the quality of the output. There is no doubt that present-day equipment is highly productive and there is just as little ground for argument with regard to the improved quality of the work turned out. All this means lower cost and increased output per man. It is these items which determine the true worth of any machine and which will amply compensate for any increase in cost. Not only will present-day equipment pay for itself in a short time through the savings effected, but it will continue to return handsome profits as long as used intelligently.

If your bevels on the top of the teeth are very acute so will your saw be more difficult to work. Flat tops are better than very acute angles, but a gentle slope gives the best results.

Band saws, when not in use, should be carefully coiled and hung where they will not be damaged. To coil turn the top part twice, then let it drop on the lower portion.

Modern Methods and the Trade Journal

by G. W. N. D.

A good trade journal—in the best sense of the word—has just as important a place in modern industry as modern equipment. Equipment may be well and good, but without the latest information on the best uses of that equipment how can one expect to obtain results which will enable him to survive the exacting demands of present-day competition? The columns of the technical educator devise and direct the best that can be produced from the material on hand.

The function of The Canadian Woodworker is to provide the latest and best practice in the several fields of the woodworking industry. In this service not only the editorial but the advertising pages are enlisted. Always it must be remembered that some of the brightest minds are to be found among those who have sufficient enterprise to spend considerable sums upon the extension of their trade connections.

Now we are persuaded that the practical men in the woodworking industries of Canada constitute the very backbone of the country's industrial establishment, and it is our constant aim to produce a paper which breathes forth this conviction from cover to cover.

The part of the reader in our scheme of things is just that bit of practical information which crops up in the trivial round and common task, and which serves as the basis of the most helpful, educational material that can be published: how this and that economy was developed in a certain plant by the use of certain equipment; how a saving was effected here and there: here, perhaps, by the substitution of a different kind of material, and there, possibly, by turning over a portion of the operation to skilled instead of unskilled labor, or vice versa. It means nothing as to how the idea is worked up from a literary standpoint. It is the idea itself that is wanted.

Modern methods within the province of the trade journal boiled down spell one word—co-operation. Co-operation between the journal and the industry,—between the journal and each individual reader and advertiser. .Co-operation with the reader; service to the advertiser. Modern methods spell co-operation, and co-operation spells efficiency.

Could You Make These Doors for $27.60?

The Other Fellows' Prices Are a Poor Basis for an Estimate—Lumber Burden Sometimes Overlooked—Comparative Figures on Set of French Doors

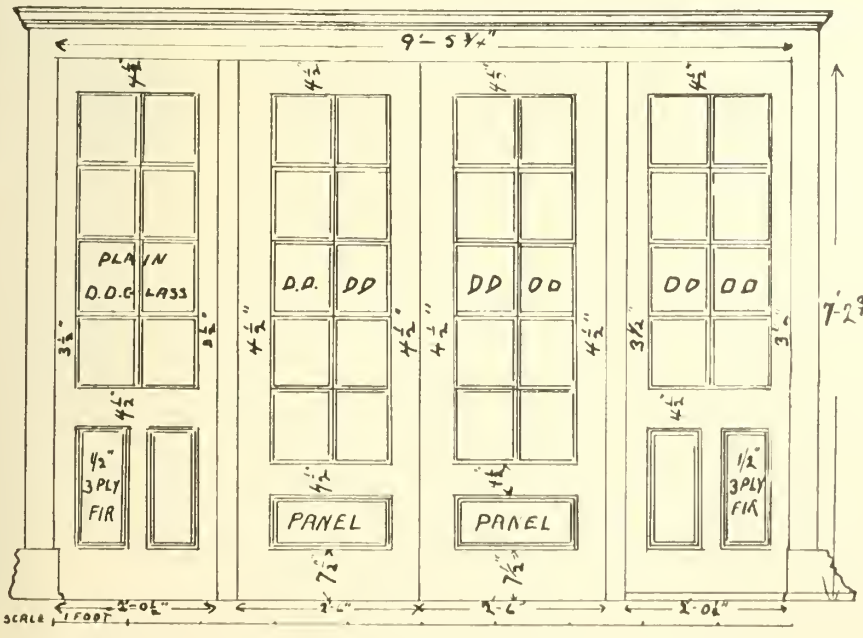
At the present time competition is extremely keen in the woodworking field, particularly in that section devoted to the production of made-to-order millwork, and as a result prices are being cut to the last notch. This condition should pre-suppose a thorough grounding in costs, so that all prices given, particularly the low ones, are based on a ground-work of accurate cost knowledge, enabling the person responsible for the quotation to make it in a reasonable and intelligent manner with a full knowledge of the anticipated profit. This is the only way in which a millwork business can be conducted with any degree of assurance as to the results of each day's efforts.

In this connection the cost studies which have appeared in recent issues of this publication should prove of real assistance. To those who do not keep cost records but who base their prices upon lists and quotations made by others or upon that uncertain basis, years of experience not backed by cost records, these articles should have a strong appeal, for through the figures given, they are able to compare their idea of prices with those prevailing throughout the industry. Even to those who know their costs, the comparative figures accompanying each article should carry a message, as to a certain extent through them the efficiency of plants, methods and departments may be compared.

Some day, and not in the far distant future, definite standards of performance will be universally recognized in our industry. These may be basic time standards for various operations or there may be some form of standard hour, but whatever form these standards may take, when once established, they will enable any woodworker to determine whether or not his particular plant and each department of his plant is above or below the general average or standard.

Before going on to a discussion of the cost estimates submitted on the set of French doors selected as the subject for the cost article in this issue, it might be well to touch on that all-important factor, lumber burden. It is doubtful if more than a few of the better-informed woodworkers realize just what this lumber burden is and how it eats into their profits if they have neglected to consider it or to take account of it when figuring costs. A careful check of many of the large woodworking plants in Canada and the United States has established with a reasonable degree of certainty the fact that it costs $6.00 per M. to store lumber in the yard and deliver it to the factory door. This figure does not include kiln-drying but is made up of such items as interest on the money tied up in lumber, handling and teaming charges in the yard; interest and taxes on the land on which the lumber is stored; upkeep of lumber yard and other items of a similar nature. If the stock is kiln-dried, a further charge of $6.00 should be tacked on to cover the cost of the drying operation. This means that kiln-dried lumber, delivered at the factory door, should carry a burden of $12.00 per M. feet. These figures may appear to some to be excessive but whether or not the correctness of this lumber burden is admitted, the fact remains that every woodworker is faced with a lumber burden, and unless he makes proper provision for it in costing and estimating, he is sure to sacrifice some of his prospective profits.

In some plants the practice is to apply the lumber burden in the form of a fixed percentage on the cost of lumber. This is not the correct method as it does



The cost study of these French doors reveals wide discrepancies in the various items involved, which should not occur were costing and estimating on a proper basis. See the comparative figures on the next page.

not give a true lumber burden. It may divide up the yard overhead and over a twelve-months' period absorb all carrying charges, but the burden itself is not evenly distributed, as 10% on mahogany costing $3.00 a M., gives a lumber burden of $30.00, while the same percentage on pine at $100.00 is only $10.00, yet the handling cost and yard burden is practically the same in each case. Thus it will be seen that the only true and accurate way to apply a lumber burden is in the shape of a fixed amount per M. feet. The amount to be applied will vary in each plant but from $5.00 to $6.00 per M. is not an excessive amount when every burden factor is taken into consideration.

The French doors, shown in the accompanying illustration, were submitted by a reader in Western Canada who has taken a great interest in these cost studies. In sending in the data covering this job, he asks if it is advisable to make the same overhead charge for the glazier as for the cabinet makers, viz., 30 cents an hour, and also if 10% is sufficient to cover the waste in cutting and handling glass. His figure of $41.85 is not very far out and at the price received for this work, a very satisfactory profit was made.

Details of Original Cost on French Doors

45′ clear E. G. fir 1½ rgh, at $70.00	$ 3.15
waste 25 per cent	.80
9 sq. ft. 3 ply fir ⅜. at 15 cents sq. ft.	1.35
waste 25 per cent.	.45
20 lts. D. D. glass 12 x 12. at 10 cents each.	2.00
16 lts. D. D. glass 10 x 12. at 8 cents each.	130.
waste 10 per cent.	.35
150 lin. ft. stops at ½ cent per lin.	.75
Machine time, 6 hours at $1.25 per hour.	7.50
Bench time, 18 hours at $1.00 per hour.	18.00
Glaziers time, cutting glass, 1 hour at 80 cents.	.80
Factory Cost.	$ 36.45

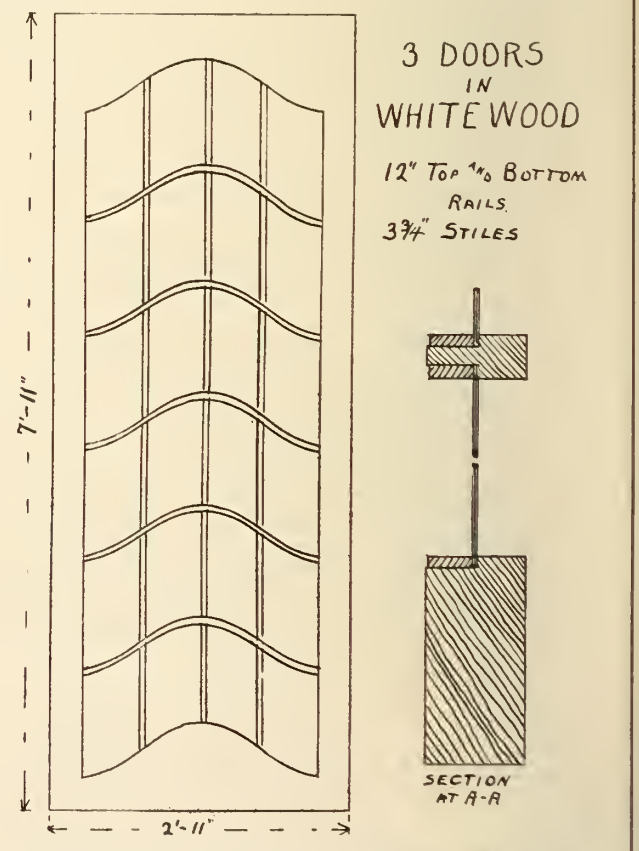
In view of the variations in material as shown in the accompanying list of estimates submitted, a number of articles dealing with the taking off of quantities from millwork orders might not be out of place. It seems strange, to say the least, that where one figures 45 feet of fir will complete this order, another estimates that 125 feet will be used. This is far too great a difference. There should be some uniform method of taking off quantities that would result in a greater degree of uniformity in the material column. The percentage of waste varies in almost every estimate. Here again there is something wrong, as the amount of waste on an order of this kind should not vary very much in different plants.

In this connection one woodworker wrote in commenting on the figures covering the set of stairs, shown in the last issue. He vouchsafed the opinion that most of the estimates published were away out as far as waste percentage was concerned, as the actual waste on a job of that kind would run anywhere from 30 to 40%. Is this right? There is little doubt that 10 and 15% wastage is totally inadequate for stairwork, but it is donbtful if 40% does not go to the other extreme. This woodworker may not be using the most desirable grade of material for his door work or his methods or workmen may be wasteful. It is always well to check one's own methods and results thoroughly before concluding that a competitor is entirely at fault. There is no doubt that many woodworkers fool themselves by not allowing sufficient for waste. Not recognizing factors of this kind, is an extremely unwise policy, because such discrepancies must be taken care of in some way or other, and if an adequate allowance has not been made, they come out of the profits.

Another special door order has been chosen as the subject for the cost study for the July issue. This, as will be seen from the accompanying illustration, is of an unusual design and entails a considerable amount of shaper work. For this reason it will be extremely interesting to see how the various woodworkers figure a door of this type. Owing to the special nature of the work, it is more than probable that the quotations sent in will show more than the usual variation. Make a point of seeing that you have a figure



The subject of cost study for the July issue—a special door job should afford interesting information. Make a point of sending in your estimate of cost immediately An unusually large list of figures is hoped for.

in for the next issue. Don't wait to be asked but send it along by the next mail. When writing in, if you have completed some work recently that you think would make an interesting cost study article, full details of the cost, together with a sketch of the job would be appreciated.

Making Glue Joints on the Linderman

One Canadian User Claims that it is the Most Profitable Machine in His Plant—Tops Jointed and Glued at $4.00 per M. Feet—Extremely Satisfactory in Hands of Skilled Operator

By GEO. H. HAWLEY

The furniture manufacturer who cuts up more than 3,000 feet of lumber per day, may consider himself as working at a disadvantage if he does not glue it up on a Linderman automatic glue jointer. In days gone by when the lumber we bought was wide enough and clear enough to almost make a whole dresser top without a glue joint, we did not feel the need of such a machine, but now that the majority of the lumber we are able to buy, and particularly hardwood lumber, is of such quality that it must be ripped up into narrow strips to eliminate all its imperfections, and these strips must be built up into pieces containing from four to ten glue joints. It is then that the automatic glue jointer becomes an absolute necessity.

With keen competition, the reduction of cost is a matter of prime importance, and even though the first cost of the machine is high, its economy in labor and material is such as to very soon pay for the machine and give large dividends on the investment. In the first place it enables us to buy a cheaper grade of lumber and build it up into first-class material at about 60% of the cost of any other method. Having been in charge of factories, where the different methods of joining wood together has been in use, most of my life, and having made a study of it, I find that the automatic dovetail glue joint is the only way to do it if we hope to keep in the lead in our line of business.

First, let us consider cost as that is the most important item to-day. Years ago we jointed our material by hand on a buzz planer, matched it up into gluing widths on a rip saw, warmed the joints in a heater and clamped together, a lot of hand clamps being used which after being left on the material for about two hours in order that the glue should become thoroughly ard, had to be removed ready for the next lot. By this method four men, if they were hustlers, could joint, match up and glue approximately two hundred dresser tops containing 1,200 feet of material in ten hours at a cost of $14.00 or about $12.00 per thousand feet. Next came the continuous feed jointing machine, which helped the situation some as it put a small tongue groove in the middle of the joint adding some strength to it, and with this machine came the rotary glue clamp carrier which helped the clamping operation some as it saved the handling of the clamps. These devices enabled four men to joint and glue up about 2,000 feet of lumber in ten hours if they hustled.

Next came the Linderman automatic machine with which to-day four men are jointing and gluing from four to five thousand feet of hardwood lumber and making a stronger joint, also ripping it to widths at the same time, in ten hours, at a cost of less than $4.00 per M. Another advantage in the use of this method is the floor space it saves us. The majority of furniture factories to-day are short of room in the machine room, and the Linderman, we find, requires just half the floor space to glue up 5,000 feet of material that was taken up by the old method. My reason for basing my estimates at four men as a gluing staff, is because that is all it requires to operate the machine, the two feeders and the operator in the middle of the machine, who when the material is wide enough, puts it into the self-feed ripping saw, installed at his right hand, and the fourth man to take it away, place it on a truck and hand the rippings back to the right-hand feeder. It is also essential for the fourth man to watch for an occasional bad joint which is generally caused by crooked or twisted material and should be ripped and run over again before it goes to the planer. Originally it took eight men to joint, glue and size up the five thousand feet of lumber that we can now accomplish with four, and it also took more than double the floor space.

One important feature is the fact that the joints do not need warming, as owing to each joint being glued and run together instantly, the glue has no chance to get cold, as is the case where six or more joints have to be covered with glue and then all placed in position while several clamps are screwed up.

Still another feature any cabinet maker will agree with me that a glue joint that is rubbed together makes a stronger joint than one that is simply squeezed together. Now the tapered wedge glue joint made on a Linderman when the dovetail is run together, causes the glue to be thoroughly rubbed into the pores of the wood and forces out any surplus glue, of which there is very little, as the brushes wipe it off the joint and put it back into the pan instead of on the floor.

I have heard people remark when they were looking at the machine at work, that it must be a very complicated machine to operate, and they would think it would get out of order, but this is all wrong. For a machine that does the fine accurate work that they do, there is very little to get out of order and the machine is more than human in the perfection and accuracy of the work it does; in fact it shows a great deal of skill and study on the part of the inventor to design the different parts in such a way as to make them almost foolproof and so simply and strongly built that with reasonably good care they will not wear out in a good many years.

The one we have, has been in constant use for nine years and we have had very few replacements to make on it. Even the spindles which run at 4,000 r.p.m., are so superior in design to almost any other machine that there is no comparison. These spindles run in tapered phosfor bronze sleeves and require almost no adjustment, are lubricated in a simple and positive manner by a high-grade lubricating grease under pressure, and are not constantly giving trouble like a babbit bearing. This machine also has the tilting bed which enables us to glue up stock at any angle or curve desired. It may be put to quite a number of

uses, such as putting stiles on the ends of desk lids and tablet slides for office desks, gluing up cores for veneered work of any thickness, and using several dovetails, it makes a superior joint for material that has to be resawed by using the double cutters and resawing between the dovetails, leaving a dovetail in the centre of each panel; in fact a very wide range of work can be done on one of these machines, especially on one with the tilting bed.

Two or three things are necessary for the making of good glue joints. First, it is essential when a machine is installed, to have an expert operator come from the factory and teach two men how to adjust and operate the machine so that if one is absent from any cause, the other can take his place. The expert should stay with the machine for a couple of weeks till he is sure that the men he is teaching are both competent to make all adjustments and understand all the different parts of the machine most thoroughly. In selecting two men for this position, care should be taken to choose men who will be likely to remain, men who are settled in the place and will be pretty sure to stay on the job. It is a great mistake to instal one of these machines and set a man to study it out for himself, and it is worse yet to let Tom, Dick and Harry run the machine and then blame the machine for the results. The same man should be kept in the middle of the machine. Any one can feed at the ends. The reason we have had such excellent results with ours is that the same man has been operating it for eight years, and the quality of our joints proves that it has paid to keep him there, and to make a long story short, after using a Linderman glue jointer for eight years, we consider it the most profitable investment in our factory.

Douglas Fir for Washer Tubs

How Suitability Was Determined—Report of Forest Products Laboratory, Montreal—Has Definite Advantages Over Metal

By W. McD. TAIT

It is a fact very well known in the lumber industry that Southern or Louisiana Cypress which has grown for centuries in the low lying lands about the mouth of the Mississippi River is becoming fast depleted. This is, perhaps, better known to manufacturers who have occasion to use this wood in the articles they produce. Washing machine manufacturers are in this class and are feeling the scarcity of cypress most keenly. It is not generally known that there is another wood which is equally as good if not better than cypress for washing machines. This brings us to the point of this article for it has been found by laboratory test and by actual use extending over a period of years that Douglas Fir is eminently suited for washer tubs.

I have before me a bulletin issued by the American Washing Machine Manufacturers' Association in which there is listed all washers sold in America. Classification as to type is not important for the purpose of this article, but classification according to material used is extremely interesting. Out of two hundred washers listed, one hundred and fifty-six made of wood. Analyzing this latter list, in five, Douglas Fir is specified as the material of construction; in one, Yellow Fir; and in another, Oregon Spruce. In the remaining one hundred and forty-nine tubs some variety of Cedar, mostly Louisiana Cypress, is used.

Admitting a shortage of cypress which, of course, must be heart or dead wood, it is apparent that very soon washer manufacturers must look elsewhere for material for tubs. Our own buyer was compelled during the last three years our firm used cypress, to go to the cypress swamps in Louisiana in order to get lumber that could be used at all in our tubs. And even this selected material did not make tubs up to the standard of our other lines.

Adapted After Thorough Tests

Fortunately our firm foresaw this possibility and about five years ago began to test Douglas Fir to ascertain its suitability. Two distinct lines were followed. In the first, tubs of Douglas Fir were made and given to employees to be used regularly in their homes. These tubs were put to varying tests. In some cases water was allowed to stand in them, inviting decay of the wood, but not even a tendency in this direction was noticed. Other tubs were allowed to stand in semi-heated places in the week between washings—this to induce shrinkage—but in no case were any leaks found after water was first put into them. They were also found, when the least air was admitted when not in use, not to mould or give off any offensive odor. It should be said here that these tubs were tested at London and Fergus, Ontarrio, where an atmosphere much dryer and more variable than that prevailing in B. C. was to be encountered.

The second series of tests were carried out for us by the Forest Products Laboratories at Montreal. These tests justified our belief that in Douglas Fir there was available a material that would fill all the requirements of a washer tub.

In writing us after the laboratory tests R. J. Blair, Pathologist, says in part:

"When wood is used for such purposes as the manufacturer of laundry tubs there are two independent relations regarding moisture which may be considered. These two conditions are the shrinking and swelling of the wood due to its moisture content and decay of the wood which results from keeping it permanently moist.

"The special advantage over Douglas Fir which Louisiana Cypress is supposed to possess is its greater resistance to agencies causing decay . It is not thought however that this consideration should be of any importance in laundry tubs. With a washing machine used once a week and stored in a dry place the tendency of the wood to decay would be so slight that Douglas Fir is quite suitable. If the wooden part of the machine is encased in a tight metal casing so that the wood might remain permanently moist the Cypress would be preferable.

"It would not appear that the difference in shrinkage of Douglas Fir as compared with that of Cypress should be of sufficient extent to make the Fir unsuitable for the manufacture of tubs.

It is worthy of note that Mr. Blair has some doubt

about Cypress possessing greater resistence to agencies causing decay than Douglas Fir, for he says "is supposed to possess" and goes on to say that "this consideration should not be of any importance in laundry tubs."

Strength a Desirable Feature

A point not mentioned in the report but which is of great importance in washers that have moving parts set on the wood work of the machine, is that Douglas Fir is considerably stronger than Cypress and should therefore stand up better against any mechanical wear to which the wood might be subjected in use.

Four of the five washers referred to as using Douglas Fir tubs are our own, and we have now had them in commercial use long enough to know that no mistake was made in our change of material. What a wonderful field must open up when the use of Douglas Fir for wood tub washers becomes general! When one stops to realize that between the years 1914 and 1919 the washing machine industry in America jumped from $7,600,000 to $50,381,000, an increase of 663 per cent, there must surely be found in the very near future a new market in the washer manufacturers of America.

There is no reasonable ground for supposing that any material will take the place of wood in any larger proportion of washers than are in use today. On the other hand there are many reasons for hoping that the proportion of wood tubs may be largely increased. The following are a few:

Is Preferable to Metal

The wood tub keeps the water hot much longer than the metal tub because wood is not a conductor of heat and metal is a good conductor. We have found that our tubs, which are 1¼ in. Douglas Fir, keep the water so hot that even after the washing you cannot allow your hand to remain in it. We have filled our tub with hot water, closed the lid, and allowed the water to stand for 24 hours. At the end of that time it was still warm. This could not be done with any kind of metal tub. Wood will always be the material used where retention of heat is desired.

The wood tub keeps the operator cool. The advantage of this will be noted any hot summer day when washing is being done in a kitchen or small room. The wood tub is the coolest tub to use.

The wood tub will not rust. This argument can be used very effectively anywhere on the coast where a damp, salt atmosphere is always prevalent. The metal tub will rust, and rust will soil and stain.

The wood tub is easy to care for after use. A dipper of water will clean it out and it is ready for use again. Soap will not corrode on it and its appearance is not spoiled by the action of soap and water. Metal tubs are often a pretty sight after they have been in use a few months.

Pioneer Western Woodworker Passes

Another of the fast-vanishing little band of "old timers" of Western Canada has passed in the person of Alex. Brown, Sr., who died at his home in Winnipeg on April 13th. Alex. Brown, or "Sandy," as he had been familiarly known to his many friends, was born in Ayrshire, Scotland, and came to Canada when a very young man. He settled in the West in 1872, and with Thos. Rutherford of Galt, Ont., formed a partnership known as Brown & Rutherford, to engage in the woodworking and lumber business. This business still exists, and from an inconspicuous start in a small factory, has developed into a large plant, enjoying an extensive trade.

The business of Brown & Rutherford is to be conducted by the sons of the two original founders of the company.

Turning Wood Waste into Dollars

When properly handled, wood shavings and hogged wood waste have a fuel value equal to 75% of that of coal. Even when hand fed, if done efficiently and with a full knowledge of all the requirements of good combustion, the efficiency of wood waste is in the neighborhood of 60% of that of coal.

To benefit from the full heat value of shavings and wood refuse, it is necessary to feed it into the fire-box without the admission of air. This can best be accomplished with some form of stoking equipment which carries the shavings into the fire-box in a steady, uniform stream and distributes it evenly over the fire. When the shavings are fed in through a spout, a large volume of air is admitted, the volume increasing as the flow of shavings diminishes. Not only must this air be heated, thus taking heat which would otherwise reach the boiler, but this large volume of cold air tends to check and retard the combustion of gases in the fire-box. With this in view, tests have shown that in many cases it costs money to burn shavings in this manner. By that is meant that less coal would be required to maintain the desired steam pressure if the shavings were not fed into the furnace, so that a larger percentage of the heat generated by the coal would be used for maintaining steam pressure.

The three main essentials necessary for the economical burning of shavings are:—First,—Continuous, uniform feeding of shavings in concentrated mass and in sufficient volume to keep grates thoroughly covered to a uniform depth but not too deep spreading over the entire grate area, carefully avoiding all bare spots through which excess air could enter. Third,—A correctly proportionate, uniformly-maintained air supply through the grates only, and by no means above the fire-box, carefully avoiding excessive amount of air over and above that required to supply complete combustion.

A properly proportionate air supply is impossible when shavings are fed in varying and intermittent quantities direct from the separator. The excess volume of air admitted in this manner serves no useful purpose but absorbs a large amount of heat since it enters the fire-box at a temperature of about 70 degrees and leaves at a temperature of from 450 to 500 degrees.

From this it would appear as if properly burned wood shavings and other forms of wood refuse are worth from two-thirds to three-quarters as much per ton as coal. In view of this it would pay many woodworkers to give greater attention to the burning of their waste material.

You can't get back a finger or a hand after it is cut off. But you can save your hand by being careful, by watching your work, by not taking a chance, by using your head, by avoiding danger.

Do You Specify Good Wood Boxes?

Do all Box Makers Pull for Their Own Product?—Extensive Publicity Movement in Favor of Good Wood Packages Under Way—Each Individual Can Help in Some Small Degree

The wood box industry of Canada, being unorganized, is not in a position to do very much to promote the use of their own product. This is unfortunate and is to be deplored. The American box men, through their organization, the National Association of Box Manufacturers, have been conducting an aggressive publicity campaign in favor of the use of wood boxes with extremely satisfactory results.

Not content to rest their case upon trade periodical advertising and direct-by-mail literature, they are making a determined effort to persuade wholesalers, jobbers and retailers to insist that all goods shipped them be packed in good wood boxes. Over 35,000 poster slips bearing the suggestion,—"Believing that the best interests of manufacturers, retail grocers and wholesalers require the most serviceable container, we request that the attached order be shipped in good wood boxes," have been distributed. The cooperage men have also decided on extensive publicity work, and both the box men and cooperage manufacturers are working under the slogan,—"Insist on having your goods shipped in the wood package."

Demand Better Packing

It has been found that the wholesale grocers of the country are almost unanimous in their desire to abolish the use of inferior substitute containers in favor of the wooden shipping package. They realize that they are being faced with large losses from pilferage, damaged and soiled goods because of the widespread use of containers which are not proving satisfactory. False economy on the part of manufacturers and shippers of various commodities is causing their customers huge losses, and the solution lies in the use of good wood packages.

Secretary Pease, of the National Association of Box Manufacturers, has been in touch with a large number of wholesalers, and in reply to a request for an outline of their experiences, he has received many pertinent communications. The following clippings from letters received, indicate beyond the shadow of a doubt the attitude of the wholesalers and jobbers on the question of proper packing:

"We believe that many manufacturers are making a mistake by trying to reduce overhead expense by using cheap packing cases. We believe that a good many products could be more profitably handled by all concerned if packed in good wooden cases, even though the first cost was a little higher.

"We have in mind one product that has always been packed in good, soft wooden cases and it has always been a pleasure to handle the goods. We have had less loss on this article from damage in transit than any other commodity we have ever handled. We refer to 'Arm & Hammer' soda and we might say that soda would carry better in fibre cases than a good many other articles that are so packed; but the Church & Dwight people seem to be far-sighted enough to continue to pack in cases that make it a pleasure for wholesale and retail dealers to handle.

"The fibre box proposition has been an expensive one to the wholesale grocer.

"We are sick and tired of losing money on goods shipped us in fibre boxes by virtue of having to stand loss and damage claims.

"The fibre container is not at all satisfactory for canned goods or any package put up in tin, because it absorbs more or less moisture which causes the tins to become discolored and rusty far more quickly than the wooden packages do.

"We are particularly against the receiving of so many goods packed in paper cartons.

"We hope that you will be successful in persuading all the canned goods manufacturers in the United States to use the wooden box, as it is by far the most satisfactory container. It is an imposition on the jobbers to ship them canned goods in paper boxes."

All Wood Users Interested

An appeal is being made to the various branches of the wood-using industry to insist, wherever practicable, that all supplies, etc., purchased be delivered in wood packages. This applies to the man who buys his oil in steel drums rather than in wood barrels or who receives certain forms of supplies in bulk instead of in boxes. All wood-users should be interested in encouraging the use of wood boxes. They stand to benefit because boxes are made from the low ends of lumber, and anything that tends to move this low-grade stock at anything like a reasonable price, will enable the lumber producer to sell the upper grades at a lower figure. To put it another way, with present conditions the sale of the better grades of lumber must pay a profit on the low-grade stock.

To bring it right home to the box industry, many box manufacturers insist that wherever possible all their supplies be shipped in wood boxes. Have you ever when placing an order, insisted that wood packages be used? If not, it is not to late to begin. This is one instance of where the individual box man can do something to promote the welfare of his industry.

Growth of B. C. Box Industry

The B. C. box and shook industry has developed to such a size that it is hard to realize that it was only seven years ago that this important industry began to grow. Before 1915 the consumption of B. C. woods for boxes and shooks was so small that it was not even given a place in government returns. Commencing with 1915 the growth and development of the box business may be traced from the following government figures which give the value of lumber manufactured into boxes and shooks by B. C. plants:—1915, $750,000. 1916, $1,833,000. 1917, $1,611,880. 1918, $1,845,195. 1919, $2,142,000. 1920, $2,650,000. 1921, $2,000,000. In the latter year, 1921, the domestic consumption of lumber for boxes was 25,000,000

feet, and the volume of box lumber exported amounted to 20,000,000 feet.

Part of this growth may be attributed to the demand for shell boxes during the years 1915, 1916 and 1917, the need being far greater than the supply. Existing plants were enlarged and new plants built and equipped. When the shell box business fell off, these concerns were forced to cater to commercial requirements to keep their plants in operation and found it necessary to seek business far afield, with the result that nearly 50% of the output of B. C. boxes is for export trade.

Attractive markets for B. C. boxes and shooks have been developed, both at home and abroad. Large quantities of shooks are required each year by the fruit packing and canning industries in B.C. Then the western product is shipped as far east as Ontario where it competes more or less successfully with eastern boxes. Many thousands are sold annually in California while immense quantities are shipped to Japan, China, Australia, India and other foreign countries.

Every imaginable kind and shape of box is made. A partial list would include the following:—Soap boxes, milk boxes, fresh fish boxes, dried fish boxes, canned salmon boxes, canned fruit boxes, jam cases, pickle cases, vinegar cases, honey cases, candy boxes, match boxes, meat boxes and crates, hardware cases, dry goods cases, fruit cases, fruit boxes, berry boxes, berry crates, tin top baskets, oil cases, butter boxes, cheese boxes, storage boxes, biscuit boxes, vegetable boxes and crates, and, in fact, boxes, cases and crates for every imaginable commodity.

The limit has not been reached for there are many desirable fields that are yet undeveloped; for instance, the tea trade in India and the middle East uses hundreds of thousands and even millions of boxes annually. This also holds true of the rubber and desicated cocoanut trade. Many of these cases are of peculiar design and construction but are not beyond the capacity of B. C. factories, and if a determined effort were made to secure a share of such business, it would help swell the ever-increasing total of B. C. box products.

Paying for Punctuality

In order to encourage punctuality and make it worth while for his employees to be ready for work before the starting time and to work right up to the closing time, one large woodworker has adopted the policy of adding one hour's pay per day to every workman who registers "in" on the time clock on or before 6.50 A.M. and 12.50 P.M. and registers "out" at 12.05 P.M. and 5.05 P.M. Under this system the employee is at his bench or machine fully prepared to start work at the stroke of the hour and works right up to the closing point without knocking off to wash up and make other preparations for leaving; in other words, he produces for the full nine hours. This works out at the rate of an hour's pay for 15 minutes of time or quadruple pay for the overtime period. Another feature is that this idea also tends to prevent congestion at the time clocks.

When you are buying trucks for moving the work in the mill, give the matter a considerable amount of thought, so you will obtain those which will give the best results.

Chart Shows Length of Belts in Rolls

By W. F. Schaphorst, M.E.

Use this chart when you want to know the number of feet of belting in a given roll.

The sketch shows how to measure the roll. The distance "X" must be measured in inches—a much simpler method than the ordinary rule as found in handbooks.

For example. How long is the belting in the roll which has 36 turns distance "X" being 50 inches.

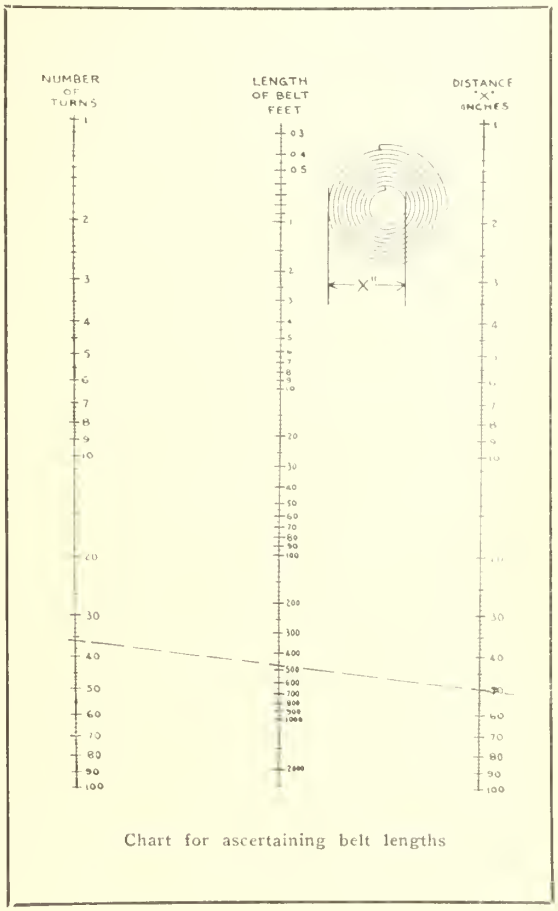


Chart for ascertaining belt lengths

The dotted line drawn across the chart shows how easily the length is found—it is 470 feet.

It will be noted that the range of the chart is very great and will easily cover any ordinary roll.

You needn't actually "draw a line" as I have done. Just lay a straight edge across from point to point and the intersection with the middle column gives the length of the roll immediately.

The method is so simple and obvious that I believe further explanation to be unnecessary. A little practice will soon make you an expert.

Credit Where Credit is Due

Through an oversight the proper credit was not given for the article on "How to look after band saw teeth" which appeared on page 65 of the May "Canadian Woodworker." This material was taken from the "Disston Crucible" an interesting monthly publication sent out by the Henry Disston & Sons, Inc., Philadelphia, Pa.

Credit Terms in Millwork Industry

Millwork Manufacturers Should Revise Terms to Meet Present Day Conditions—Net Thirty Days or One Per Cent Ten Days Should be the Limit—Contracts for all Forms of Special Work

By J. A. LOETSCHER*

Credit is probably the greatest single factor in our industrial and commercial life. It is one of the basic fundamentals that has really made American business possible. The granting and receiving of credit by our business men has, no donbt, been responsible, in a greater degree, than any other individual influence in the rapid development of our country. Even our large net work of railroads, which really made this development and expansion possible, was almost entirely built on credit. Without credit, business would still be done on the small scale of the olden days, and the business man would still be an insignificant trader, given to barter. Credit, more than any one other thing, has made possible the modern big organization with its up-to-date systems. It has also given us the big manufacturers, recognized on all sides as the great captains of industry.

In discussing this subject of "credit," I believe we were to take for our text, more specifically, the question of credit terms and discounts. In recent years there has been a decided tendency to shorten credit terms. This change was induced and helped along by developments due to the war.

Long terms were started when there was a real necessity in the early days of the development of the country, banks were small and few, and real money very scarce. But, this has all been changed. Farmers sell their products largely for cash, and as a class, except for the present period of re-adjustment, have never been so prosperous as in recent years.

Evils of Long Terms

Labor is paid weekly, twice a month, or occasionally monthly, so why should they not pay their bills in the same way as they go along? Long and easy terms tend to make people live beyond their incomes; or even to go to still further extremes, and indulge in wild orgies of extravagance and foolhardy speculation. If we shorten the selling terms, just as much merchandise, at least in our business, will be bought and used and the greater part of the money is more apt to be earned before it is spent. Again, the policy of short terms and prompt settlements will do the retail dealer a real service, since it will develop better business methods and show him a shorter road to prosperity, and thus perhaps even save many of them from ultimate failure.

"Sixty days" terms mean at the very least two months' business on your books and ours. "Thirty days" terms should mean only one months' business on the books. If we can reduce our outstandings or investment in book accounts, we will be able to improve our condition by borrowing less money. Business then will have more money available for expansion and development. Money will be easier and more readily find its way into new buildings—particularly new homes, which are needed so urgently. The best authorities estimate that the country is short about a million and a half homes.

Since the country has only been building on an average about three hundred and fifty homes per year, we should have four or five peak years some time in the near future, when things get started again in a normal way, and especially is this case, if, in addition, we knock off twenty to twenty-five per cent. of the present deficit or shortage of homes.

Short Terms becoming Universal

Many different lines have already adopted the "Thirty Days" terms. With many manufacturers, such short terms have been of long standing. In our own business, plate glass has been thirty days net or one per cent. for cash in ten days, for twenty-five years or more. Nevertheless, we always allow the trade two per cent. cash discount. Practically all our tools and shop supplies of every nature, in fact everything in the metal line is sold on terms of thirty days net. Only occasionally is some item billed on a basis, allowing us one per cent. for cash in ten days.

In recent years, or to be more exact, about eight years ago, the window glass manufacturers also adopted shorter terms, allowing us only one per cent. for cash in ten days, or thirty days net. However, notwithstanding these changed conditions, we continue to allow two per cent. cash discount, though the glass and glazing represents fully seventy to seventy-five per cent. of the value of every glazed sash sold to the trade. Then, too, in order to earn our one per cent. discount, we are "required" to make payment within ten days from date of invoice, of at least ninety per cent. of the invoice price, notwithstanding the car may be in transit from three to six weeks, and frequently, owing to congested traffic conditions, as much as two months.

Many Items Not Subject to Discount

But there are a few items, which none of us as manufacturers, can discount, namely: Wages, freight paid on raw materials, insurance, taxes of various kinds and degrees, traveling and other expenses, and salaries, interest, etc. This account of cash discount, therefore, is always a "red ink balance" shown on the wrong side of the ledger.

Wages alone generally average from twenty-five to thirty-five per cent. of every Sales Dollar, depending somewhat on the nature of the work and whether or not the volume is made up largely of stock stuff or a varied line of special millwork, covering plan work and the like. Freight paid out for raw material and other incoming shipments also will average from twelve to eighteen per cent. of the total sales.

Another reason why we should shorten our selling terms and reduce outstandings, is because the present market, due to the war and existing abnormal and continuing inflated conditions, has added very materially to the value of our inventories. In other words, we are all obliged to tie up more money in the stocks we

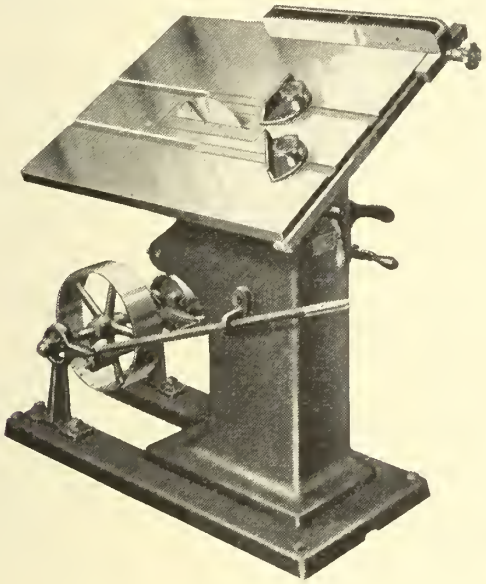
Machinery & Equipment

"Williams" Light Variety Saw

The accompanying illustration shows a "Williams" light variety rip and cross-cut saw, as recently put on the market by the A. R. Williams Machinery Co., of Toronto. It was designed particularly for use on light cabinet work and for the assembling department in furniture factories and woodworking plants. The frame is cast in one piece and has an extended sub-base which carries the countershaft. Provision is made for adjusting the countershaft so as to take up all slack in the saw belt. The table is 29 x 32

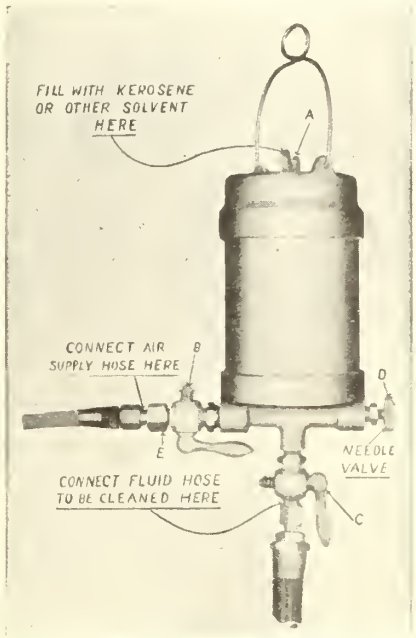


A. R. Williams light variety saw table

inches with a wood throat piece 11 x 3 inches, permitting the use of dado cutter. The table will tilt to an angle of 45 degrees. The ripping gauge may be used on either side of the saw. Material up to 12 inches wide may be ripped on the right-hand side of the saw, and stock up to 8 inches on the left-hand side. Saws as large as 11 inches in diameter may be used, enabling stock up to 2 inches in thickness to be ripped. The saw is raised or lowered by means of a lever and swings from a pivotal point on the back of the frame. The machine is extremely easy on power, requiring only from 1½ to 2 h.p.

Hose Cleaning Device

It is not a very easy matter to keep the hose of the spray nozzle clean and free from hardened finishing materials. A device which will help overcome any trouble that may be experienced in this direction has been recently put on the market by the DeVilbiss Mfg. Co., Toledo, Ohio. This is shown in the accompanying illustration. It consists of two brass castings connected by steel tubing. The lower casting carries the air inlet valve, the outlet fluid and air valve and the fluid needle adjusting valve. The upper casting is funnel-shaped to facilitate filling and has a wing nut to close the opening. The cleaning device is filled with some suitable solvent which is permitted to flow into the air line, the amount going through being controlled by the needle valve, where it is thoroughly mixed with the air. A combination of air and solvent

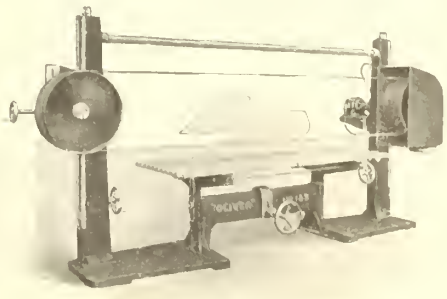


Hose cleaning device for sprayers

being forced through the spray hose, quickly removes all finishing material which may be clinging to the interior of the hose, and ensures that the hose is thoroughly clean. The claims made for this device is that it lengthens the life of the hose, cleans it quickly, ensures quality spray work and prevents a loss of solvent through evaporation.

Reversible Belt Sander

The new No. 183 reversible belt sander, recently placed on the market by the Oliver Machinery Co., Grand Rapids, Mich., is designed for the rapid sanding of line and edge moldings, straight, flat and ir-



Oliver reversible belt sander

regular surfaces and for sanding and finishing built-up pieces such as cedar chests, chairs, kitchen cabinets and all kinds of medium size pieces of furniture. It will take work of any length and sand to the center

of 72". It will take work on the table 42" high or by unbolting the table, 66" high from the floor. The table travels 36" horizontally and adjusts 14" vertically. Belts about 31' long and any widths up to 10" may be used. The pulleys run in ball bearings. The machine is convenient for the operator and quick in operation. The spokes in the one wheel are guarded and on the other end the pulley is entirely enclosed in the exhaust hood. The table mentioned above rolls on ball bearings and not on ball bearing rollers. Reversible switch permits the belt to run in either direction. In general it might be said that the machine consists of three principal parts—the power stand, idler stand and the table. The table is fastened to the base plates of the stands, all carefully machined and mounted in perfect alignment and overhead the two stands are connected with a rigid bar or top stay. The sand pulleys run in ball bearings. The table is 96" long and 32" wide. For motor drive slow motor is directly connected to the driving pulley, pulleys being rubber faced, running at 600 r.p.m. These pulleys being very large in diameter make for longer life of the belts as the sand breaks off less than when going around a small pulley. The pulleys are 24" diameter by 10" face. High Speed motor may also be geared to the pulley.

Heavy Fire Loss at Huntsville

Fire recently destroyed the entire woodworking enterprises of the Muskoka Wood Mfg. Co., Limited, Huntsville, Ont. The blaze is believed to have originated from a smoker in an outhouse. A high wind was blowing at the time and the fire was not noticed until it had communicated with the dry kilns. The sawmill, woodworking factory, storage sheds, power plant and all other buildings were wiped out.

Fortunately the lumber escaped. R. J. Hutcheson, president and managing-director, reports that the loss is very heavy as they have between 4,000,000 and 5,000,000 feet of logs at the mill yet unsawn, about half of the logs being hardwood.

The Muskoka Wood Mfg. Co. have not yet decided what they will do in the future, but owing to the assistance of friends in the trade, they are taking care of all flooring orders. The insurance on the plant amounted to $162,500. The company have been successful financially, and if they decide to begin reconstruction, one of the most modern factories on the American continent will be carried out. The plant had been running steadily during the winter months and was behind in shipments of flooring, "Red Deer" brand flooring was turned by the company, and the product is well known from Coast to Coast.

The Muskoka Wood Mfg. Co., Limited, was organized in 1902 and erected a small sawmill and woodworking plant at Huntsville. During the first year thirty men were employed aind at the time of the fire two hundred and fifty were on the pay-roll. The business has grown steadily. The company cut in the sawmill about 6,000,000 feet and produced 3,000,000 to 5,000,000 feet of hardwood flooring each year. The Muskoka Wood Mfg Co. also turned out lath and had a dry kiln capacity for about 250,000 feet at one time, and storage room for 1,000,000 feet of flooring.

The sawmill and factory were equipped with up-to-date machinery and a large dressing in transit business was done for a number of lumber firms. The power plant was of solid brick construction 40 x 40 with Waterous boilers carrying 115 lbs. of steam and developing more than 600 h.p. The boiler house was equipped with a Robb Armstrong and one each Waterous high speed and Filer & Stowell Corliss engines. The latter had been installed recently and would develop 750 h.p. It was the intention of the company to install further boiler capacity.

At the time of the fire the company were engaged in erecting an extension to their flooring plant, about 80 x 150 feet, and the walls of this building were up as high as 12 feet.

The Muskoka Wood Mfg. Co. had five kilns, two forced-draught and three natural-draught kilns. The plant covered about fifteen acres and there was a piling ground for 10,000,000 feet of lumber. There are eight railway spurs on the property which has splendid booming grounds, docks, etc.

Sweep of the flames at Muskoka Wood Mfg. Co.

Do not blame the boy for all the faults caused by a saw which is worked without any tension.

Upholstering and Trimming

Deep Seat Type of Chair

Probably Most Luxurious Style of Upholstered Furniture—Frame Made Without Feet

The chair illustrated in Fig. 118 brings into our discussion of modern upholstering perhaps the most luxurious type in modern use. The deep spring upholstering of this seat does away entirely with chair feet and the chair rests directly upon the floor.

In addition to this feature, this chair is of unusually luxurious proportions which must be built up entirely in upholstering.

For this reason, the seat of the chair is double-stuffed, and a soft, stitched edge is provided above the wire of the spring edge, as shown in Fig. 119. The stitching of the edge is intended only to give shape to the edge, not hardness.

The next step is the upholstering of the arms, as shown in Fig. 120. These arms, as will be observed in the illustration of the finished chair, Fig. 124, serve only the purpose of elbow pads, but they are completely upholstered, because, when in use, the down cushion and soft, spring seat sinks with the weight of the occupant, exposing the inside of the arms. They must, therefore, be treated as if they were exposed at all times. Fig. 120 gives the appearance of the arms at this stage.

The next step is the springing up of the back, which has been thoroughly described in connection with other chairs. This is followed by the double-stuffing indicated in Fig. 121, with its soft, stitched edge. The purpose of this edge and double-stuffing is to bring the depth of the upholstering of the back to about equal the thickness of the down cushion, in other words, the frame and stitched edge combined should equal about four inches, and the down cushion should also be four inches, so that the entire back, as shown in Fig. 124, is about eight inches thick over all.

A soft coating of hair is laid over the entire back. This may be confined under a muslin covering or it may be kept in place by the down cushion, which, as shown in Fig. 123, can be sewn to the stitched edge, it having been first fitted and filled in the manner already described in connection with other chairs.

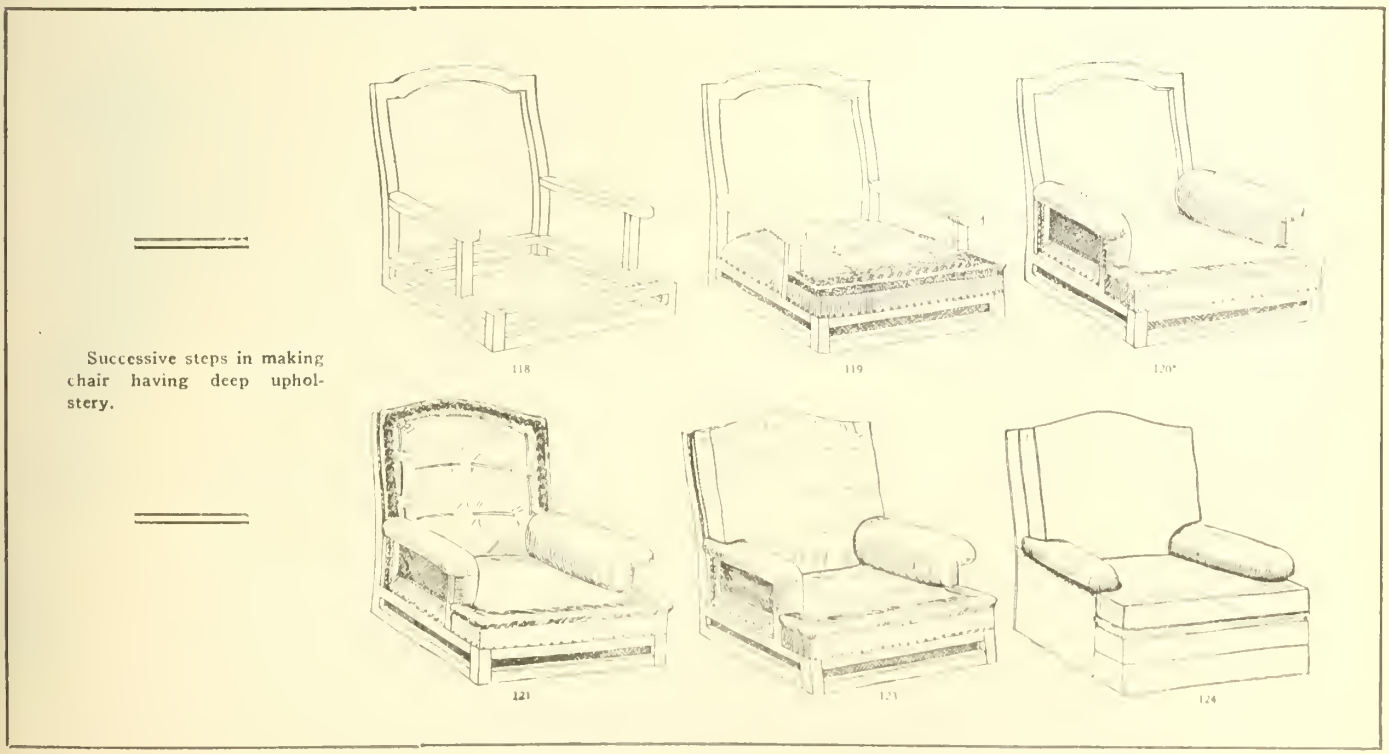
The completed chair, shown in Fig. 124, gives the appearance of the chair finished by welting. The luxurious character of the upholstering is suggested by its appearance of double and triple cushioning as well as by its unusual size.

(To be continued.)

Buying Burlap by the Pound

Many Interesting Questions Discussed at Recent Meeting of Upholsterers' Association

The National Association of Upholstered Furniture Manufacturers held a mass meeting in Chicago recently at which a number of unusually interesting topics were discussed. All subjects on the agenda



Successive steps in making chair having deep upholstery.

were frankly and fully thrashed out and in most cases definite conclusions were reached.

When the question of free samples of upholstering fabrics was brought up, it was recommended that all manufacturers of upholstered furniture confine their samples to pieces 6 in. x 6 in. If larger samples are required they are to be furnished to the dealers actual cost. It was brought out that many upholsterers are sending out samples as large as 24 inches square, which is a very costly method of promoting sales. President Gorrell, in reciting his experience, stated that 34 sample books recently made for customers cost him slightly in excess of $1,000., and that his records showed that for every $100,000. worth of merchandise sold the samples cost in the neighborhood of $1,000. From this it will be seen that the uncontrolled distribution of large samples costs the manufacturer a considerable sum each year.

Discourage Breaking of Complete Suites

Attention was also directed to the fact that manufacturers of cotton bats charge for the gross weight of the bales which means that the purchaser pays in many cases from 18 to 20 cents per pound for the burlap coverings. Definite action was not taken on this subject but it was the consensus of opinion that each manufacturer should, in purchasing cotton bats, specify that the net weight of the bale, after the covering had been deducted, would be the basis of settlement.

Members of the Association are to have their attention drawn to the question of making odd pieces to complete broken suites. One member present brought to the attention of the gathering the fact that as the appearance of pile goods changes rapidly when subjected to light, it was almost impossible to make an odd piece to match a broken suite on the dealer's floor even when covering taken from the same bolt is used. For this reason it was recommended that the manufacturers of upholstered furniture refuse to fill any broken suites and also that the manufacturers explain to their customers the necessity and advisibility of selling complete suites.

Should Not Present Conditions

D. D. Fennell, the executive secretary, in discussing general business conditions, attributed considerable of the present unsatisfactory state of affairs to the expansion of manufacturing facilities which took place during the period through which we recently passed. He pointed out that the normal increase of employment from 1899 to 1914 averaged 2.7%, while from 1914 to 1919 the yearly average increase was 5.3%, which is an increase of over 100% of normal. From this it will be seen that many who were not ordinarily wage earners were induced to enter the manufacturing field, so that to-day there are to be found plants and equipment able to produce upholstered goods far in excess of the normal demand. It was his opinion that upholstered furniture manufacturers should adjust themselves to present conditions rather than worry because conditions do not adjust themselves to their ideas as to what business would be.

In touching on the wage question, it was shown that in 1913 the average wage in the upholstering industry was less than 25 cents per hour, while to-day,

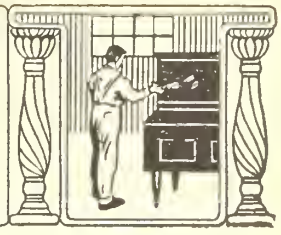
THE FINISHING ROOM



Saving $22,000.00 in the Finishing Department

An Annual Saving of this Amount Has Been Effected in One Large Plant Through the Use of Varnish Drying Equipment

A stroll through the finishing rooms of several furniture factories is sufficient to convince one that many furniture manufacturers are alive to the advantages and savings made possible through the use of varnish drying kilns for the quick drying of varnish and other finishing materials. While some furniture men cling to the older and slower air-drying methods, many of the more progressive have kept abreast of the times and are enjoying the benefits and advantages of artificial drying. A comparison of the old and the new methods usually shows that where from twelve to sixteen days were required to finish a piece of high-grade furniture when all coats were air-dried, but six to eight days are necessary when resort is made to artificial drying.

Recently the Drying Systems Incorporated of Chicago, had a report made on the installation of Greeff varnish dryers in the Norwood, Ohio plant of the Globe-Wernicke Co. Extracts from the report show that an annual saving of $22,000. is being effected through the use of varnish drying kilns and that 350,000 pieces pass through the kilns each year at a cost slightly in excess of 2½ cents per piece. Some interesting extracts from this report follow:

Substantial Saving Shown

"Our Greeff system dryers have more than cut in half the time required to finish our furniture. This means that they have easily effected a 50 per cent reduction in floor space, saving $15,000 a year in rental, and have also reduced the amount of work in process of finishing by $100,000, saving $7,000 a year in interest charges. This gives us a total of $22,000 a year, making a return of 300 per cent on our investment," says George F. Kroeger, general superintendent of the Globe-Wernicke Company, Norwood, O.

"These dryers have the additional advantage of enabling us to carry most of our stock in white, which greatly reduces the risk we formerly assumed in anticipating which of our 20 to 24 different finishes would be ordered. Also by baking the filler hard, the dryers give the right foundation for the finish, and insure excellent results in the final coat. Since their installation we have had no trouble with sweating when we rub the final coat, and there is much less dust in the finish.

Natural Drying is Uncontrolled

"The finishing rooms had always been the most troublesome part of our plant, and the finishing process was always the one which held up production. We could control the production speed in all our other processes, but in finishing we were at the mercy of weather conditions, and production delays due to bad weather were very frequent.

"Following a visit to another furniture factory, where we found Greeff dryers successfully handling a process similar to ours, we decided that these dryers would supply the missing link in our manufacturing process.

"We installed one stain and filler dry room, and one varnish dry room early in 1915. Later that year we put in another stain and filler dry room and another varnish dry room. In the latter part of 1916 we installed one high temperature green enamel dry room for enamel work on our steel cabinets. The total floor area of the first four kilns is about 10,000 square feet.

Seven Day Schedule

"These four dry rooms are used for finishing wooden filing cabinets and bookcases, of which we are one of the largest manufacturers in the world. A dull rub job gets three coats; a polished finish gets four coats. We use a temperature of 110 degrees on the dry bulb and 80 degrees on the wet. Our schedules vary somewhat, but they average about as follows:

Monday—Stain, two hours in kiln.

Monday—Fill, eight hours in kiln (over night).

Tuesday—First coat varnish, six hours in kiln.

Wednesday—Second coat varnish, six hours in kiln.

Thursday—Third coat varnish, twelve hours in kiln.

Friday, Saturday, Sunday—Dry and set.

"We usually let the last coat dry for twelve hours to be sure it is hard, and then let it set for two days to get it acclimated. Thus every coat is thoroughly dried, insuring an excellent finish. The entire process takes approximately a week. For thirty years we dried our furniture in ordinary rooms, the complete process requiring from two or two and a half weeks. The process of introducing moisture with heat effects a big time saving and gives a better product.

Operating Cost Extremely Low

"Our steel work, which has an oak and mahogany finish, is dried in one of the varnish dry rooms, using a temperature between 140 degrees and 150 degrees, but the green enamel finish, which constitutes the larger part of our steel work, gets three coats, and is dried in the room especially designed for it. The process takes about three days. If we used the air drying system for our green enamel it would be impossible to use the kind of enamel now employed, because it would practically never dry. If we used an enamel which would dry in the air it would be at a sacrifice in quality.

"The cost of operating the dryers is very low. The installation of four stain, filler and varnish dry rooms amounted to $7,080.00, exclusive of the dry room housing, and the equipment is easily good for ten years. It takes only one man to handle the work

in and out of each dry room. A small amount of power is required for operating a connected load of fifteen horsepower. The only other expense is for the steam required for heating. As we used some steam under the old system this is not all additional expense.

"The total annual operating cost of the four dry rooms is $9,080.08. Working 300 days per year, the cost is $30.27 per day. Since we handle 350,000 pieces a year, the cost per piece is $.0259. Costs on the enamel drying room are not available."

While the Greeff varnish drying kilns are manufactured by the Drying System Inc., Chicago, their license permits them to sell only in the middle and western states and in Canada. The A. S. Nichols Co., of New York, produce their varnish drying under the same patents but their field is limited to the eastern states and eastern Canada, including Ontario.

Maintaining a Standard Finish

Requires Careful Attention to Shade and Tone to Maintain a Standard—Drying Schedule for High Class Finish—Use Only One Grade of Varnish

At different times the question of adopting recognized standard shades for the various finishes found in the furniture industry has been discussed and many arguments have been put forward in favor of certain definite standards being adopted. One of the chief objections, however, is that if some such move were made many lines would lose one of their distinguishing characteristics, viz., individuality in tones and finish. Often the finishng room foreman or the man responsible for the mixing of the stains and fillers will strike some new and unusually attractive shade or tone that will immediately find favor, resulting in an increased demand for that particular line. Special finishes of this nature have proved to be such efficient sales incentives that instances are not lacking where considerable sums of money have been offered for the "secret" of certain attractive shades. This advantage would be lost if standard finishes were to come into general use.

There is one branch of the furniture industry, however,—manufacturers of desks, filing cabinets and sectional bookcases,—which has adopted individual standards that are rigidly adhered to. This is absolutely necessary because a desk or section purchased to-day must often match up with furniture bought, perhaps, some years ago.

Not Easy to Maintain a Standard

A maintaining of a standard shade is not quite so easy a matter as one would think. It is so easy to lose a particular shade or tone especially when two or more men are working on it. This was the experience in the plant of the Office Specialty Mfg. Co., of Newmarket, Ont., when in 1919 and 1920 they were pushed to the limit to keep up with their orders. This unusual rush of business necessitated that the duty of maintaining the standard shades be delegated to three finishers. All were supplied with sample panels of the required shades and each one came very close to these standards, but when the output of one man was compared with that of one of the others, there was a marked difference in the strength of the finish. It was found that one was working just on the light side, another on the tone, while the third was just on the dark side. Comparing the output of each man with the sample, the difference was not noticeable to any but an experienced eye, but when the products of the light and dark men were compared the contrast was very marked.

The mixing of stains and fillers, especially in a case of this kind, is a one-man job, that is, the maintaining of any desired shade or tone should be left entirely to one man. Even when that is done, unless he is frequently called upon to work with that particular tone, his eye will soon lose its ability to hold the required shade. This even though he has a standard panel with which to work.

Use Combination Stain and Filler

At the present time the Office Specialty Co. are using a combination stain and filler on their oak line. This is dried in a Cutler varnish-drying kiln. The drying of the filler or foundation coat in this way results in a very satisfactory base being secured for the varnish coats. After the filler has been dried, a coat of white shellac is given, followed by three or four coats of varnish, depending on the quality of the finish desired. All desk tops are given a four-coat finish.

The varnish coats are artificially dried in a kiln having a dry bulb temperature of 90 degrees to 95 degrees, giving a relative humidity of about 35%. These are approximately the same conditions as are found in the panel-drying kiln. Under these circumstances there is no tendency for the veneers to check or the veneer joints to open in the varnish-drying kiln for the equilibrium moisture content of the conditions in the varnish-drying kiln is practically the same as the equilibrium moisture content of the veneer-drying kiln.

Drying Times for Varnish Coats.

The initial coats of varnish are given eight hours in the kiln and forty hours air drying before the next coat is applied. This means that each of the foundation coats are hard and dry before the next coat is spread on. The second last coat, however, is only given eight hours in the kiln before the final or rubbing coat is applied. The reason for this is that applying the finishing coat before the preceding coat is thoroughly dry, enables the two coats to knit together, practically making one heavy coat. This will withstand a lot of rubbing, such as is often found necessary to bring up a large surface like a desk top. If the first coat should happen to be rubbed through in spots, it will not be noticeable for the two coats are as one, whereas if the under-coat had been perfectly dry before the finishing coat was applied, each spot where the finishing coat was rubbed through would be plainly visible.

Another thing that has been standardized in the finishing department of this plant is the grade of varnish used. They use one grade, and that the best, for all lines and for all coats. This is as it should be for

the saving which may be effected by using cheaper varnish for either the under or finishing coats or both, is very small and is more than offset by the standard of the finish secured. As the finish goes a long way toward selling an article or a line, it would pay many manufacturers to change their policy and by buying better material, turn out a line with a finish that will give a satisfactory amount of service.

Enamels for Furniture Work

By Chas. V. Eddington.

The main feature of enamels for this class of work are uniformity in shade, brushing consistency, flowing, drying and rubbing. Of course, uniformity in shade is absolutely essential, as the furniture manufacturers require to turn out different pieces that will match in shade.

In the past it has been the custom for manufacturers of general lines of paints to endeavor to make furniture enamels, which will no doubt account for the unsatisfactory enamels which have at times offered to the furniture trade. These enamels require unusual care, and a knowledge of finishing room conditions in order to turn them out satisfactorily.

The pigment portion must be exceedingly fine, and the vehicle is a special varnish made for this class of goods that dries harder than the ordinary enamel vehicle.

As a rule three coats are used, namely: two of the undercoat and one of the enamel, although in some cases it will be found that the second coat will consist of a mixture of the undercoat and the enamel. In high class work four coats are generally used, namely: two of the undercoat and two of the enamel.

The enamel can be obtained in either satin or high gloss. the high gloss is a rubbing enamel, while the satin gives a rubber enamel effect and is intended for cheaper grade work. Both the undercoats and the enamels can be either brushed or sprayed, and can be used in a forced drying system with satisfactory results. They can be used on either wood or metal.

SELLING FORCE OF GOOD FINISH

It may stand every strength test, this table or chair,
May be built like a gunboat, for service and wear;
May be made from the finest of metal and wood,
Yet may lack one essential—and never make good.
Though its inner construction be sound as a bell—
If the finish be wrong, 'twill be harder to sell.
The design may be perfect, original, bold,
Its beauty and grace a delight to behold.
Or again, it may copy with scrupulous zeal
Some design on which genius of old placed its seal.
Neither form, nor affection for fashions antique
Will put over the sale—if the finish be weak.
Make sure of the finish you give it, say we,
And see how much better its "FINISH" will be.
—"Marietta Message."

Information and Inquiries

You are cordially invited to make use of this department

Clothes Pin Equipment

Sorel, P. Q.,
April 27th, 1922.

Editor, "Canadian Woodworker."

We would like to get some modern clothespin-making equipment and also a hub wheel machine, and thought perhaps that you might be able to tell us where this machinery might be secured.

Would also like to know where we can secure some rock elm at some point near Sorel.

Sincerely yours,
C. Boisvert & Sons.

Clothespin equipment may be secured from the following concerns:—The Humphrey Mfg. Co., Keene, N. H.; W. H. Smith Mfg. Co., Sunapee, N. H.; or the Goodspeed Machine Co., Winchendon, Mass. It is just possible that some of these manufacturers may make hub wheel machines. We are not in a position to give you any information with regard to the rock elm, which may be available near Sorel. Can you not make a few inquiries among sawmill men in your vicinity? If they do not cut this wood, they will, likely, be able to tell you the nearest point at which you can secure it.

Varnish Works
Montreal Toronto Winnipeg

with the new course on estimating by the Millwork Cost Bureau, of Chicago, I would like very much to take this course but do not happen to be a member or in the employ of a member. Can you tell me how I can secure this estimating course?

Sincerely yours,
H. C. Evans.

You might write the Millwork Cost Bureau, 605 N. Michigan Ave., Chicago, Ill., and see what they have to say with regard to sending you the course. We are of the opinion, however, that the distribution of this estimating course is confined entirely to members of the Bureau and their employees.

Cost System Wanted

Editor, "Canadian Woodworker,"

We are running a Sash and Door factory together with a retail lumber yard and would like to know of a system whereby we would have a better and more accurate knowledge of our production costs. However, it is not our intention to install an elaborate and costly cost keeping system. What we want is a system that would give us all the necessary information without requiring the services of extra clerical help. Will any of our subscribers who already have had such a system in operation let us know how this is run or where this could be bought?

Yours truly,
Latour et Dupuis, Incorporee
By R. M. Boisvert, Accountant.

Here is a chance to help a fellow woodworker, and at the same time assist in promoting cost knowledge. Send in an outline of the cost system you are using and describe its operations. It would be gratifying to be able to publish brief descriptions of several simple but practical systems in the July "Canadian Woodworker."

Calculating Speed of Pulleys

Joliette, P. Q.,
May 8th, 1922.

Editor, "Canadian Woodworker."

Can you give me the rule for calculating the size and speed of pulleys. Suppose I have a motor running at 1,800 R.P.M., with a 5-inch pulley and want to run a machine at 150 R. P. M., what size pulley would I require on the machine.

Sincerely yours,
R. T. Brazeau.

A pulley 60 inches in diameter, if driven by a 5-inch pulley on a motor running 1,800 R.P.M., will give you a speed of 150 R.P.M., which is what you require. The rule is the R.P.M. of the driver shaft divided by the desired R.P.M. of the shaft to be driven, and multiplied by the R.P.M. of the driver pulley. If you are figuring the other way, and had a shaft with a certain sized pulley upon it, which you wanted to drive at a certain speed from a shaft of a known speed, you would reverse the formula and work the other way.

If you have a large number of small articles to turn get the advice of our advertisers who specialize in turning machines as to whether they can make you an automatic lathe to turn them.

The wood finish that will not paper mark in shipment

A product finished with ZAPONITE, the Pioneer Wood Lacquer, is proof against the harmful effects of paper marking when wrapped and packed for shipment.

Being extremely hard and uneffected by moisture, heat and climate changes, a ZAPONITE finish never gets "sticky," it never paper marks and it never shows the imprint of burlap wrappings—another reason why ZAPONITE is the ideal finish for quality products made from wood.

Let our Service Division help you to determine how ZAPONITE can be used in finishing your products at a SAVING in your production costs. Write us about this service TODAY.

Set Outside Your Varnish Room

The money a Nichols Paint and Varnish Dryer saves will pay for the equipment in one year.

This is not a wild statement but one we have proved time and again to manufacturers in practically every branch of the woodworking industry.

The Nichols Vertical Paint and Varnish Dryer is a complete unit of fan, motor, heaters, air compressor, with automatic humidity and temperature controls. A new rotary, humidifying air washer which eliminates all dust and dirt and does away with all spray heads, pump and connecting piping.

The equipment is manufactured in sizes suitable for all requirements.

Let us analyze your particular needs and quote prices on same.

A. S. NICHOLS COMPANY

33 West 42nd St., New York City

Manufacturers of dryers for lumber, veneers, glued stock, varnish, paints, enamels, etc.

Increasing the Speed and Decreasing the Cost of Your Finishing Room Operation

How practical, how advantageous and how dependable DeVilbiss Spray-painting equipment is, has been demonstrated in finishing rooms of every size and line.

Not merely in dozens of finishing rooms, but in thousands of them. Not only where a few different kinds of articles are handled, but where every kind, size and grade of wood or metal product is finished. Not alone where varnishes, enamels or lacquers are used, but where every kind of liquid finishing material is applied. The

DeVilbiss

Spray-painting System

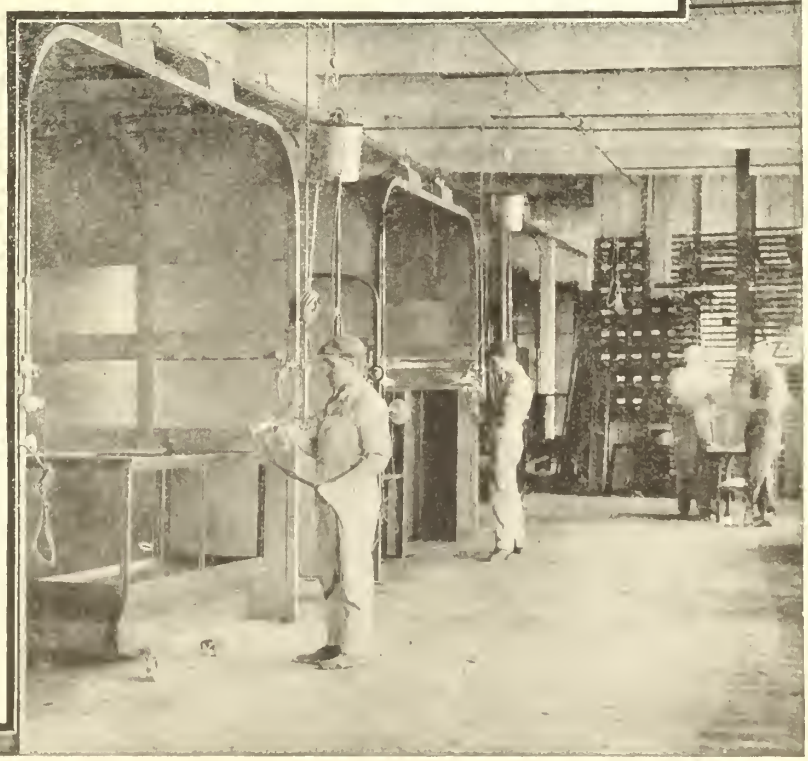
offers a complete, adaptable and guaranteed service. The finishing operation is speeded up 4 or 5 times over hand-brushing. A perfect, uniform coating is applied on all jobs. Working conditions are made more healthful and safer. Operating and upkeep costs are reduced to the minimum.

With your consent, we'll gladly tell you whether and how the DeVilbiss System can be of service and profit to you.

The DeVilbiss Mfg. Co.

3718 Detroit Ave. ***Toledo, O., U.S.A.***

Paint your factory walls faster and better with the DeVilbiss Spray-painting portable equipment. Let us explain.



FACE VALUE
A certain famous painting is valued at fifty thousand dollars, and there is much speculation as to whether it is worth the amount. The average man would not part with fifty thousand cents for its possession, its value as a thing of beauty is not apparent except to a few connoseurs.
The beauty of Birds Eye Veneer is unquestioned in the minds of both the unschooled and the educated. This beauty has a face value in the open market that none can dispute. Incorporated in your product it will add to the value of the piece in equal proportion as it enhances the beauty.
Use Birds Eye Veneers for beautiful furniture.

Glue Room Economy and Technology

Suggestions for Applying – Overheating or Prolonged Heating Weakens the Glue

By R. H. BOGUE*

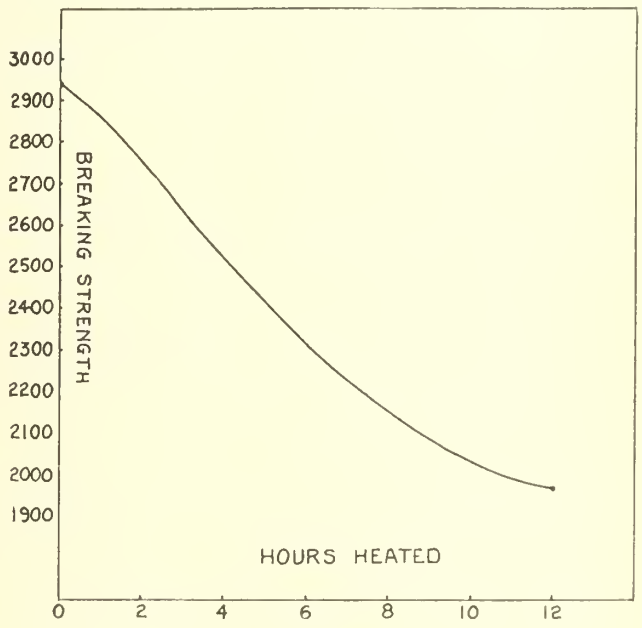
(Second of series)

After due consideration has been given to the concentration of the glue solution to be used for a certain work, the joiner must see to it that the joint is true, that the temperature of his glue is correct, that the temperature of the wood is correct, **i.e.**, warm but not hot; and then apply his glue quickly, rubbing it in as if he were painting it; apply the glue to both sections of wood in the joint; rub the joint to squeeze out as much of the excess glue as he can; and apply the pressure quickly and uniformly before the glue can have time to set. It has been shown that the most favorable pressure is about 200 pounds to the square inch of glued surface, but in practice only about 30 pounds are ordinarily employed. The joint should then be placed in a warm dry place and allowed to remain undisturbed for 8-12 hours. It is then safe to remove the pressure, but the maximum strength is not developed for several days.

Losses in Glue Due to Overheating

It was not many years ago that it was a common practice among joiners and cabinet makers to procure the highest quality of glue, and boil it down to obtain a particular consistency which was regarded as most desirable. They argued that in order to do the best work a glue must be of the highest grade, but that such glues, on the other hand, were too thick to spread well at the dilutions they regarded as necessary, and also chilled too thickly. It therefore became common practice to cook the material until it did possess the desired qualities.

A number of experiments have been performed in the writer's laboratory which illustrate very strikingly the decrease in strength which is brought about by the prolonged heating of a glue. Samples were made up in the usual way by the use of one part of glue to two and a half parts of water, and were heated for twelve hours in a water bath maintained at a temperature of 176 degrees F. All loss in water due to evaporation was made up each hour. At the beginning of the operation, and at the end of two, four, eight, and twelve hour periods, portions of the glue were removed and applied to maple blocks which had been very carefully surfaced, and the glued joints subjected to a uniform pressure of 200 pounds to the square inch by placing between the parallel plates of a universal testing machine. After sixteen hours they were removed, allowed to set for a week, and then carefully sawed to exactly four square inches glued surface, and sheared apart. The data obtained show very forcibly the serious loss due to prolonged heating, for the value of the glue dropped approximately one grade for each two hours of heating, or from the highest to the lowest hide grade in twelve hours. In actual figures the loss in strength averaged about 85 pounds per square inch per hour, or about 1,000 pounds per square inch in the twelve hours. Differently expressed, the loss in strength amounted to more than 5 per cent. of the original strength per hour of heating, or to 67 per cent. loss in the twelve hours. The curve expressing the decrease in strength is shown in Fig. 1.



Curve indicating how prolonged heating reduces glue strength

This is not an exceptional case, for many other investigators have found somewhat similar results. For example, Linder and Frost working at the somewhat lower temperature of 150 degrees F. (65.5 degrees C.) obtained a decrease in strength of from 30 to 45 per cent. on heating a glue for 20 hours. The United States Forest Service has conducted similar tests. Solutions of a high grade joint glue and a veneer glue were heated for 48 hours at 104, 140, and 176 degrees F. (40, 60, and 80 degrees C.) and tested every few hours during this period for strength and viscosity. "In the first 7 hours of heating at 176 degrees F., the veneer glue lost approximately one-half its joint strength, and the high grade glue joints weakened almost as much. The greatest loss in the strength of the glue joints occurred at this temperature. In the

*Industrial Fellow of the Mellon Institute of Industrial Research and Research Chemist for Armour & Co., Chicago.

This article represents a part of the section of the "Glue as an Adhesive" in the writer's forthcoming treatise on "The Chemistry and Technology of Gelatin and Glue," to be published by the McGraw Hill Company of New York in the Summer of 1922.

solution kept at 104 degrees there was a sudden drop in the strength of the joints made with the high grade glue after 31 hours of heating, due possibly to a combination of bacterial and chemical action. The veneer glue joints showed a more gradual decrease at this temperature. The most favorable of the three temperatures used was 140 degrees, but even at this temperature an appreciable weakening in both glues was noted at the end of 7 hours, and longer heating caused greater loss." The viscosity of the two glues decreased rapidly throughout the experiment.

Consider for a moment what these losses mean in dollars and cents. The price of the highest grade of glue is about 50 cents per pound, (in barrel lots), and the price of the grade to which it was brought by twelve hours of heating (in the writer's experiments) is 23 cents. That is, a loss of 27 cents per pound is sustained in twelve hours, or a little over two cents per pound per hour. The average loss per day of eight hours would, therefore, amount to about nine cents per pound. Let us carry the proposition to its conclusion. Suppose the amount of glue kept heated at all times is approximately a hundred gallons. That will represent perhaps 400 pounds of dry glue, and during the day the loss will become, therefore, 9 x 400 or $36.00. In the course of a year this rises to the surprising amount of twelve thousand six hundred dollars. Surely the prevention of such a loss is well worth a little time and thought.

Joints May Not Hold

Glue does not deteriorate by standing for 12-24 hours in cold water (unless an already putrid glue is used, or the temperature of the water is allowed to rise above 70 degrees F.). And glue that is properly soaked may be brought into a condition ready for use very quickly by merely raising the temperature to 140 degrees F., with stirring. There should be no difficulty experienced, therefore, in keeping the amount of glue actually in solution down to just above the quantity which will be immediately used, and so entirely eliminating any loss from prolonged heating.

Of even more serious importance than the foregoing is the possible failure of the joint which is made from the weakened glue. As was previously stated, the loss in strength amounted to about 67 per cent. of the original value. Assuming that the necessary strength was 2,500 pounds to the square inch, and that the glue was bought to carry 3,000 pounds to the square inch, thus giving a 500 pound margin of safety, any depreciation beyond this 500 pound margin would be disastrous. But, in the case cited, a six hour heating resulted in a 500 pound drop! The glue user has learned to buy upon a high margin of safety, and failures are not as common as might be expected, but when one does occur the user invariably concludes that he was sold an inferior glue, that the lot in question was not up to his previous buys,—that the glue manufacturer had "put one over" on him. Would it not be well for him to look rather to his glue-room?

May we not also properly ask why it should be necessary for the user to allow such a wide margin in strength for safety? The fact that he does is in itself an admission that his use of it is uncertain; that he does not at all times get his full value out of the material. Just as soon as he has learned to control his modus operandi to the end that he shall get the full value from his glue, just as soon may he in confidence and with safety cut down his strength margin to a narrower limit, and buy a less expensive glue, or apply his original glue at a greater dilution,—a procedure which will again save him many dollars on his glue bill in a year. The only reason, in fact, why glue failures under the conditions described are not many instead of few is that as the heating is in progress, so at the same time is evaporation taking place, and instead of an original fifty gallons there will be left after several hours heating only, perhaps, forty-five gallons.

(Concluded in July issue)

Veneering Under Ideal Conditions

Newmarket Plant Boasts Unusually Bright and Attractive Veneer Department—Special Kiln for Drying Veneers and Built-Up Work—Surroundings Have Effect on Output and Cost

The methods and equipment of the other fellow always afford an interesting study, not so much because of the ideas and information which may be picked up, but because to the practical man anything pertaining to his own particular line usually claims his attention. Let us then in imagination take a trip to the plant of the Office Specialty Mfg. Co., Newmarket, Ont. and visit the panel-making department. There are several features about this particular department which should appeal to the average woodworker.

Edge-Glue All Face Stock

Upon entering the veneer room of this plant the first impression is that of a large bright, well-ventilated department. The ceilings are high, the walls are almost a continuous sheet of glass, and every part of it is bright and clean. This in itself is unusual for so often the veneer room is stuck in some little-used or out-of-the-way portion of the factory building where both light and ventilation are bad. In this case the veneer department occupies the whole lower floor of one section of the plant.

At one time the Office Specialty Mfg. Co., Limited, purchased most of the built-up tops and plywood used in the production of their line of high-class desks and filing and sectional cabinets. This has all been changed. They have developed a well-equipped veneering department, and to-day are building up all their own plywood. The output of plywood is sufficient to take care of all the ordinary requirements of the plant, though several years ago when the demand for furniture was at its peak, they found it necessary to purchase some tops and panels.

The equipment of this department consists of a Perkins glue spreader for vegetable glue; a Jenkins veneer jointer, which, by the way, is supposed to be the first Jenkins jointer to be brought into Canada; a Black Bros. veneer taping machine, manufactured

Unexcelled Facilities for Kiln-Drying

WOOD-MOSAIC COMPANY

INCORPORATED

LOUISVILLE, KENTUCKY

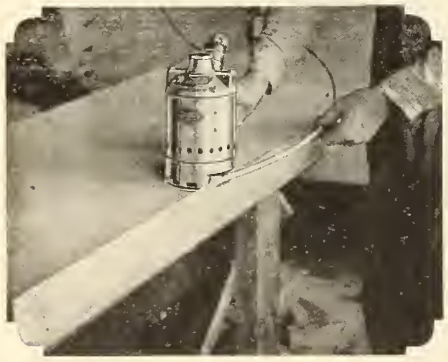
Veneering Under Ideal Conditions

(Continued from page 82)

by the Preston Woodworking Machinery Co.; a number of large sized screw presses; a C. M. C. belt sander; 2-trim saws; veneer clipper; warming oven and Cutler veneer and panel-drying kiln. A small auxiliary wood roller has been attached to the glue spreader in contact with the top glue roll. This is used for edge gluing the joints in the face veneers. Just before the face piece is run through the spreader, the tape joints are folded back and the edges run over this small wooden roll. This insures that a certain amount of glue is applied to the edges of the different pieces of veneer.

How Laying is Handled

In the laying of desk tops, which are built up on a heavy chestnut core, the oak tops are laid in one operation, that is, the crossbanding and face stock is glued at the same time. In the case of the mahogany tops, two operations are employed, the crossbanding being laid at one time and the face stock later on. The reason for this is that the heavy oak face veneer is thick enough to stand heavy sanding should the



Mattison edge veneer trimmer

crossbanding lap or buckle be used, whereas the thinner mahogany stock would be sanded through and the top ruined. The same procedure is followed in the case of five-ply oak and mahogany panels, the mahogany being laid in two operations.

After the tops have been veneered they are trimmed to size, standard wooden templates being used, and the end and edge veneers applied. This is done by hand clamps and special cauls or heavy strips. The next operation is trimming the edge stock. This is done with a Mattison edge veneer trimmer which is a small saw mounted horizontally on a small motor. This instrument does extremely smooth and accurate work as well as saving a lot of time. Formerly it took two men nearly fifteen minutes to clean off and smooth up the projecting edge veneers, but with the Mattison trimmers, one man can do the trick in about two minutes. The saving is obvious.

Veneer Dryer Kept Busy

As yet little mention has been made of the veneer and panel dryer. This is used for several purposes, such as drying the veneer, crossbanding and rotary cut core stock before laying, and for removing the glue moisture from the veneered tops and plywood. The wet and dry bulb temperatures carried are 90 degrees and 120 degrees, giving a relative humidity of 35%. The veneer and crossbanding, which is carefully piled with sticks between each sheet, is left in the kiln for 48 hours, which insures that it is thoroughly dry by the time the glue is applied. In drying the veneered stock the heavy tops remain in the kiln for 72 hours and the thinner stock for 48 hours. At the present time the purchase of a hot plate redryer for handling the thin stock and rotary cut core material is under consideration.

The matching of the veneers for the desk tops is an operation requiring a high degree of skill as well as artistic ability of no slight degree. A desk top with poorly matched veneers would not enhance the reputation of the producer. For this reason every attention is given to artistic matching. The work of the artisan responsible for this operation is made easier by the brightness and cleanliness of his surroundings.

Under conditions such as these, bright airy surroundings, good equipment and plenty of floor space, the workmen should have every incentive to produce a satisfactory volume of well-executed work, or, to put it in another way, the workmen should not have any reason for not producing a fair amount of work. In addition where conditions like these prevail, the production of high quality built-up work in a satisfactory volume should be secured at a comparatively low cost.

Quality Veneer in Demand

There is a growing tendency on the part of veneer users to buy their stock on a quality rather than a price basis. In years gone by veneer was veneer, and the manufacturer who could offer the cheapest product, usually got the business. The fallacy of this policy was soon discontinued with the result that there has been a growing demand for quality material, that is, for veneers which have been cut and graded carefully and which work up into a satisfactory product.

To insure that one secures the best obtainable, it is advisable to shop around a bit, dealing with the outstanding firms who emphasize value and quality rather than price. Take those advertising in this publication. They must have faith in their product or they would not spend good money to attract trade which they could not hold. It might be a good idea if those who buy their veneers from little-known concerns, would check over some of the advertisements found in this issue and see for themselves the quality of the stock carried by "Canadian Woodworker" advertisers. When a manufacturer is willing to stand behind his product, the purchaser does not take any great chances.

What is Mahogany?

Under the name of "mahogany" the wood of more than 60 different kinds of trees has at one time or another been marketed, according to the Forest Service, United States Department of Agriculture. Most of these woods come from the tropics, but sometimes even American birch and red gum are used in furniture and sold as genuine mahogany. For the benefit of those who wish to be able to identify the various kinds of woods likely to be called mahogany, the United States Department of Agriculture has issued a bulletin which tells how each may be distinguished.

Botanists class as "true mahogany" only trees of a single genus, called "Swietenia," of which 5 species are now known. True mahogany in this sense grows only in tropical America, from southern Florida and

(1778)

northern Mexico to northern South America, including the West Indies. But the same region furnishes other woods which may take the trade name of mahogany, as may also various woods from Africa and the Philippines, some of which are rather near relatives of true mahogany.

Those who wish to tell for themselves what kind of tree a piece of "mahogany" actually came from will find in Bulletin No. 1050 of the United States Department of Agriculture, the Identification of True Mahogany, Certain So-Called Mahoganies, and Some Common Substitutes, by Arthur Koehler, specialist in wood structure of the Forest Service, a carefully constructed key and detailed descriptions of the properties and structures of a considerable number of species of woods which reach the American markets under this name. A hand magnifying glass and a piece of the wood which can be cut to show structure and color are all the equipments needed to apply the key.

British Development in Gramophone Design

The gramophone is, comparatively speaking, a modern invention, but the last few years have seen considerable progress made towards the perfection of the instrument so far as its mechanical properties are concerned. The advances which have been made in the design and construction of motors, sound boxes, etc., and in the records themselves make it possible to reproduce both vocal and instrumental music with great fidelity, and though further improvements are, of course, possible, it must be realized that a very great deal has been done in this direction, says a writer in the "Cabinet Maker." But as the gramophone has become more popular, so it has taken its place not only as a musical instrument but as an article of furniture, and it must be confessed that the same progress has not been made in the design and construction of gramophone cabinets as is apparent on the mechanical side. If the gramophone were merely a musical instrument like the cornet or the flute, and only on view while actually in use, its design and decoration would not call for any great thought, but, as has been said, the gramophone is tending more and more to take its place to-day as a permanent piece of furniture in the room, and for that reason it calls not only for mechanical perfection but also for beauty of design.

It is true that in the production of the better class gramophones good work has been done in providing, so far as the more expensive models are concerned, cabinets which harmonize with certain periods of of furnishing, but finality has certainly not been reached. The accompanying illustrations may be regarded as a genuine attempt to design and construct gramophone cabinets which shall be really attractive, carried out with a degree of artistry and craftsmanship only possible by placing quality first and foremost, the whole being still treated as a musical instrument of the gramophone type. The centre illustration, shows a cabinet designed and constructed in the Chippendale style in mahogany, with carved ornamentation. The panels are veneered with fancy mahogany, quartered, and the upper front panel is enclosed with a painted flower subject study after the painter Van Huisman, finished on a rich old gold background. The model on the right is in the style of Louis XV. the groundwork being painted and finished in an antique cream color with carved and silvered enrichments. The upper panel is decorated with a hand-painted miniature after Nattier, a Court painter of the Louis XV period, suspended in a caned panel. The lower panel contains a painted subject illustrating the dancing of the minuet; the side and back panels are decorated with scroll and floral ornament, ormolu mounted, finished like old silver. These mounts are reproduced from models by Cafferi. The third cabinet illustrated is also in the Louis XV style. The wood used is fine figured kingwood with quartered panels of rich padouk, fitted with two Vernis Martin panels painted on a gold background. These panels are reproduced from paintings by Boucher, the famous French decorative artist of this period. The cabinet is enriched with choice ormolu mounts. Apart from all these aesthetic considerations, the manufacture of such cabinets as these is doing at the present time a great deal of good in opening new fields of work for cabinet makers and others in allied trades.

Three examples of British gramophone design

Bending Southern Oak Chair Posts in Hot-Plate Bender

(Continued from page 56)

should be carefully dried down to 12 or 15 per cent. of moisture, with a view to obtaining normal shrinkage throughout the piece, and the material should be free of surface checks and honeycomb.

2. All posts to be bent together should be the same length.

3. They should be steamed at atmospheric pressure for not more than three-quarters of an hour.

4. They should be loaded into the steam plate bender and bent as quickly as possible—within three minutes at the most.

5. If possible the radial faces should come in contact with the plates while the post is being bent.

6. Enough compression parallel to the grain stress should be applied to bring the neutral zone on the convex side of the post.

7. The steam pressure in the plate should not exceed 20 pounds.

8. The posts should be dried down to a moisture content at equilibrium with shop conditions before they go to the shaper.

Prominent Furniture Manufacturer Passes

James E. Souter, Hamilton, Ont., for the past 22 years, general manager of Malcolm & Souter, Limited, furniture manufacturers died recently at his home in Hamilton, in his 57th year. Born in Aberdeenshire, Scotland, deceased was brought to Canada when three years old by his parents who settled on a farm near Burlington. In 1882 the family moved to Hamilton where the late Mr. Souter learned the trade of cabinet making. His advancement to the position he held before his death was the reward that generally attends conscientious effort. Besides being a successful business man Mr. Souter was an enthusiastic church worker and took a great interest in the welfare of the young people. He is survived by his wife, two daughters and one son. Two brothers also survive him A. M. and D. A. Souter, of the A. M. Souter Furniture Co., Hamilton.

Good Market for Shooks

Last year Mexico imported box shooks from U. S. manufacturers to the value of $2,000,000, and it is estimated that the figure will reach $2,500,000, during the present year. What is to prevent Canadian shook manufacturers, especially those in a position to make water shipments, from sharing in this trade?

The largest purchasers of wood box shooks are, probably, the various oil companies, acting through their purchasing agents. Among the purchasing agents for the largest buyers are Samuel Kamps, purchasing agent for the Pierce Oil Corporation, 25 Broad St., New York City; L. Carr, vice-president of the Anglo-Mexican Petroleum Co., 65 Broadway, New York. These companies are the largest users of boxes in Mexico. This does not, however, cover the whole field as manufacturers of soap, macaroni, vegetable oil, biscuits, candy, cigarettes, etc., use large quantities annually.

This photograph was taken of our exhibit at the Indianapolis Industrial Exposition held in Indianapolis last fall, which was attended by more than 150,000 people. Our exhibit was pronounced the finest display of Hardwoods and Veneers at the exposition.

WE HAVE THE FOLLOWING VENEERS READY FOR IMMEDIATE SHIPMENT:

1-20" Qt. Sawed White Oak
1-16" Qt. Sawed White Oak
1-8" Plain Sawed Red Oak
1-8" Cherry
1-8" Walnut
1-28" Walnut Sliced

HAY & CO., Limited Woodstock, Ont.

Credit Terms in Millwork Industry

(Continued from page 68)

have been accustomed to carry, both as to raw material and manufactured product. For these reasons, millwork manufacturers find they require more money and capital than ever before to carry on their operations. Hence, the urgent necessity of trying to curtail our outstandings by shortening the terms of sale, and thus reduce the book accounts from two hundred and two hundred and fifty per cent. of a month's business, to more nearly one hundred per cent. of a month's business, or perhaps even a trifle less. By co-operating in this matter, we will be releasing money or credit to be used in other directions.

What Discount Amounts to

It is high time that the cash discount is reduced to one per cent. and the selling terms shortened to thirty days net. Especially is this the case, because we are obliged to accept very largely such terms on the small part of our total volume of business which really can be discounted. A careful analysis of the "Sales Dollar" plainly shows that the millwork manufacturers should revise their selling terms to meet present changed conditions.

One thing is certain, it behooves everyone of us to discount our bills, even if we have to borrow money to do it. After all, most rates of discount allowed, no matter how small, generally earn a very fair interest rate. We are not fair to our Own Business when we fail to earn the cash discount for it. Nor are we Fair to the other man's business if we take a cash discount we have not earned.

Quoting the following discounts, with the annual interest rates to which they are equivalent, will tell you why.

½% 10 days—net 30 days is equal to 9% interest per annum.
1 % 10 days—net 30 days is equal to 18% interest per annum.
1½% 10 days—net 30 days is equal to 27% interest per annum.
2 % 10 days—net 60 days is equal to 14% interest per annum.
2 % 10 days—net 30 days is equal to 36% interest per annum.

I believe most manufacturers have now adopted the latter terms, 30 days net, 2% off for cash in ten days, which means we are allowing our customers a rate that is earning them 36% interest. So even if we reduced our cash discount to 1%, as recommended, we would still be allowing the trade a liberal rate of interest, equivalent to earning 18% per annum.

And when speaking of selling terms, much might also be said in favor of the Trade Acceptance, notwithstanding this method of settlement has been in ill-repute in sime quarters. The trade acceptance has been condemned recently because the instrument has been used in collecting past due accounts, which in many instances have been renewed. It has also been claimed that many trade acceptances have been returned unpaid. However, in considering the value of the trade acceptance, it is only fair and just that we compare it with other methods of settlement. We will, no doubt, all admit that during this present period of business depression, all methods of payments have been seriously abused.

Special Terms and Contract for Special Work

Thus far we have referred principally to the matter of terms in our relations with the jobber and dealer. Most of the membership of this Bureau is probably made up of manufacturers, who are largely interested in selling special or custom made millwork direct to the contractor or owner. It has been our experience that this class of trade should really be handled on a different basis. The very nature of these operations makes it well nigh impossible for the average contractor to discount his bills within the usual required time. So few contractors have sufficient capital to undertake the large jobs they frequently attempt to handle, that they are invariably dependent on the payment of monthly estimates to take care of their current bills. This procedure and the incident routine necessary, generally means delays which preclude any possibility of payments within the usual discounting period. It has been our practice, therefore, to always quote these jobs net thirty days. In order to take advantage of and secure the protection of the lien laws of most states, it is advisable not to quote terms beyond thirty days.

We also consider it essential to draw up contracts, covering this class of business, using our own regular printed form for this purpose. We dislike to use some of the so-called standard forms furnished by the architects or the contractors themselves. They invariably are ambiguous, and generally contain a number of clauses referring to sub-contracts, which really have no place in the contract of the party furnishing the millwork. Some of these paragraphs, in these general contract forms—were they not such a serious matter—might well be considered a joke. Only last week we were obliged to turn down a fair size contract offered us by an Indiana contractor, because his contract form contained any number of perfectly ridiculous propositions when applied to the millman in the general terms of a sub-contractor. One of these clauses even provided for pro rating elevator expense, also the insurance—fire, tornado and compensation insurance—among the sub-contractors on a basis proportinonal to the amount of their contracts. Surely items of this kind have no place in the contract of the millman. As stated, we returned this contract together with one of our blank forms, further outlining our ideas, and suggesting just what we think such a contract should cover. Thus far we have not heard from him. We have probably lost the business, but are just as well pleased. We know our competitors are going to do business and get their share of the trade, so we prefer they deal with this class of customers that seem to be a little obstreperous, and are inclined to have everything very much their own way. Most of us generally have enough grief and trouble without deliberately inviting it by signing some of these unreasonable contracts that are put before us. It is foolish to thus court or borrow trouble. We will gladly mail a copy of our contract to everyone who is sufficiently interested to apply for a form.

Much might also be said on the subject of a modified form of blanket bid, such as is used by many of the members among the larger mills, but I will refrain from any further remarks, since I have already taken up too much of your time and imposed on your good nature. For the purpose of discussion, therefore, I would suggest the following terms for the jobber and the dealer, namely: net thirty days, or 1% off for cash in ten days. For the contractor, terms of net thirty days.

The July "Canadian Woodworker" will contain an article by O. W. Brightman of the Green Bay Planing Mill, Green Bay, Wis., discussing Mr. Loetscher's address and outlining the views of the smaller planing mill operator.

Suggestions of Live Current Items

The usual famous Anderson-Tully service stands behind every foot of the following list of specials which we are pleased to offer the buying trade:

QUARTERED WHITE OAK

4/4 FAS 150,000

Full product of the log in this grade. Stock containing all of the 10" and wider produced, average 7½" for width, 45% to 55% 14' and 16' lengths.

4/4 No. 1 Com. & Selects .....150,000'

Full product of the log in this grade. 45% to 55% 14' and 16' lengths. Stock 8 to 12 months dry.

QUARTERED SYCAMORE

6/4 No. 1 Com. & Bet ..... 75,000'
5/4 No. 1 Com. & Bet. ..... 40,000'

Sycamore is beautifully figured stock, band sawn and equalized, 7 to 8 months dry. 55% to 60% 14' and 16' lengths. All wide in this stock.

LOCUST

4/4 Log Run .....One Car

SOUTHERN SOFT MAPLE

5/4 Log Run .....100,000'
(Worm holes no defects)
10/4 Log Run .....100,000'
(Worm holes no defects)

PLAIN RED OAK

5/4 Common & Select .....60,000'

PLAIN SAP GUM

5/8 FAS .....150,000'

PLAIN SYCAMORE

5/8 No. 2 Com. & Bet.....100,000'
6/4 No. 1 Com. & Bet. ..... 100,000'

Both items running 60% long lengths. Band sawn and equalized and 7 to 8 months dry.

HACKBERRY

5/4 No. 1 Com. & Bet. ..... 150,000'

Band sawn, thoroughly dry, and high grade in every particular.

HICKORY

8/4 No. 2 Com. & Bet. ..... 200,000'
6/4 No. 2 Com. & Bet. ..... 100,000'
10/4 No. 2 Com. & Bet. ..... 20,000'
12/4 No. 2 Com. & Bet. ..... 30,000'

WILLOW

We make a specialty of Willow in 4/4 to 8/4 thickness, and have a stock of this wood. We particularly want to move

4/4 No. 1 Common ..... 200,000'
5/4 FAS. ..... 40,000'
6/4 No. 1 Com. & Bet. ..... 100,000'
8/4 No. 1 Com. & Bet. ..... 50,000'

All of this stock thoroughly dry.

Discriminating buyers will find that it pays to be linked with an organization and service so truly founded on an understanding not only of the manufacture of lumber, but of its proper merchandizing and utilization.

Buying Burlap by the Pound

(Continued from page 72)

exclusive of the metropolitan districts, it is close to 40 cents per hour. Though wages are 90% higher to-day than in 1913, the price of upholstered furniture is only 42% above the 1913 level.

Well Planned Publicity

The Davenport Bed Makers of America then held a meeting. Discussion centred chiefly on the publicity campaign being put across by the davenport men. This is not a mere flash in the pan but a steady aggressive, well planned, advertising campaign which will bring customers into the dealer's stores for the next few years at least.

R. Branner, who is directing this campaign said; "There are five distinct elements that must be reached, and each is as important as the other. Starting with the manufacturer, he must help us to train his salesmen to sell service with davenport beds. The man on the road must not only sell the product of his house, but he must help to sell the goods when they are once in the dealer's store. He must endeavor to create a davenport bed expert in each store—a clerk who believes in the value of the piece, and who, because of this belief, will be able to impart it to his prospective customer. We must then help the dealer and keep him alive with sales suggestions, window cards, etc. We are doing this in our little magazine, Turnover, which will be sent each month to over 15,000 clerks and retailers, letters, letter inserts, etc. Then will come the clerk, and, as he is the final outlet to the customer, we must spend a large amount of time on his training. Finally we reach the customer who has been attracted to the store by our advertising and the dealer's window display."

Condition of Southern Sash and Door Industry

The response ai a number of suggestions submitted to the members of the Southern Sash, Door and Millwork Manufacturers Association by the secretary C. B. Harman, indicate that conditions are fairly good in that territory. The questions and replies are as follows:

	Good	Fair	Poor
How are orders with you now	22	33	6
How are enquiries with you now	35	23	3
What are prospects for business now and July 1st.	28	30	3
What are the prospects for the balance of the year	31	24	3
How are collections	8	37	15
Are you working full force	40 Yes		21 No
Are you working full time	50 Yes		11 No
Is money fair for construction purposes	41 Yes		18 No
Is your business what you would call normal	27 Yes		32 No

Develops Teamwork and Personal Interest

The stronger the co-operation between employers themselves and between the employees and the management, the less the confusion and fewer the broken promises. It creates a personal interest, develops teamwork and promotes the best interest of the company by having a better understanding of what to do if unforseen delays occur. It helps to meet competition, it cements the organization together and makes each department feel its part of the responsibility and to feel their ideas and suggestions are respected and appreciated, that each and every individual is a part of the great organization and has a hand in its growth and development.

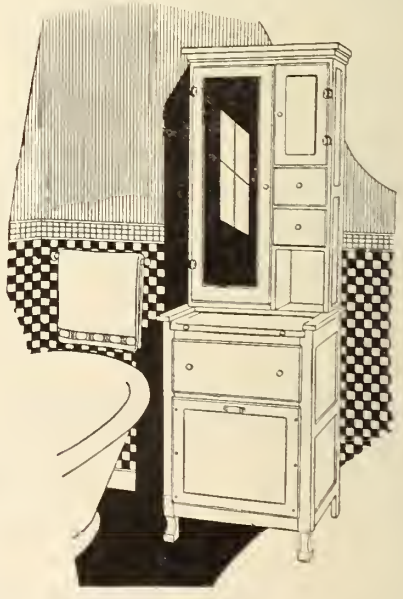
Co-operation between the different departments of an organization brings profits, the lack of it means loss. Teamwork gives greater impetus to business than anyone thing.

Hardwood Flooring Plants Busy

Hardwood flooring manufacturers are busy. Recently the head of a large concern stated all their plants were running to capacity and that one was operating both night and day. The prices on all lines are well maintained and there have been a few upward revisions of late. The present house-building campaign had resulted in a strong demand for birch, maple and oak flooring. The requisitions for the latter still lead, it being the most popular of all floorings for homes. A number of owners are, however, using birch and maple for upstairs and kitchen requirements. The speaker stated that special lines of hardwoods would be very scarce within the next two or three months and he predicted that there would be a decided shortage of maple in all grades, while the better ends of birch would be none too plentiful. Some export business is being done in hardwood flooring but not to any great extent.

Something New in Bathroom Furniture

A new piece of furniture for the bathroom, which has been placed on the American market recently, is shown in the accompanying illustration. This takes the form of a large bathroom cabinet and is in reality the application of the kitchen cabinet idea to bathroom requirements. As noted in the illustration, it consists of an upper and lower section, the upper being fitted with a large mirror and numerous small compartments which serve the following purposes.—medicine cabinet, shaving outfit compartment, toilet articles compartment, and provides space for various other



articles. The lower section, which is fitted with an extension, porcelain enamelled top, is provided with a large drawer for clean towels and a hamper for soiled towels and soiled linen.

While no dimensions are given, this would probably be from 26 to 30 inches wide and about 6 feet in height. When finished in white enamel it would make an attractive addition to any bathroom.

The method and character of our sticking is ne reason why our lumber is straight and flat"

DISCRIMINATING BUYERS

Now recognize the advantage of a dependable source of supply for their lumber and realize that quality, reliability and uniformity are the most important factors of cost.

These desirable features can only be supplied by the conscientious and reliable mill; they are beyond the control of the dealer, or middle-man, who must of necessity draw his supply from many different sources and can exercise no influence over the manufacture, handling or grading of the merchandise he sells.

Our lumber is properly graded; every board is plainly marked showing the grade for which it is shipped, and likewise bears our brand.

THE KRAETZER-CURED LUMBER CO.

We are manufacturers exclusively. Every board that we sell is the product of our own mills, and is manufactured, handled and piled with the greatest care; no expense is spared to obtain the best results; all our energies are directed toward producing a product that will yield maximum results to our patrons. The very highest quality in Gum, Oak, Ash and other Southern Hardwoods cut from virgin growth Delta timber.

KRAETZER-CURED GUMWOOD *Because:-*

. It is STRAIGHT and FLAT, free from the warp and twist usually encountered in untreated stock.

2. It is BRIGHT and will satisfactorily take any finish.

3. It is free from dote or rot—the sap and gums are eliminated by the steaming process and fermentation and decomposition are thus prevented.

4. Through the elimination of stain and decomposition, it possesses greater strength and longer life.

5. It contains only atmospheric moisture, enabling it to be used for many purposes without kiln drying.

6. When kiln drying is necessary, this can be done in much less time and with more satisfactory results.

7. It is uniform and dependable. One car like another, grade and measurement what it should be—no time wasted in reporting complaints or shortages, no delays or interference with factory schedules because of holding lumber for adjustments.

8. It is the most economical lumber available. It will satisfactorily answer any requirements expected of materially higher priced woods. Join our little army of satisfied users, and just as peace is about to supplant war, let peace of mind take the place of the warfare and worries that usually beset the user of lumber.

We're proud of this product that's why.

The Kraetzer-Cured Lumber Co.

GENERAL OFFICE- GREENWOOD, MISS

Band Mills: Greenwood, Miss., Moorehead, Miss.

The Lumber Market

Domestic Woods

The general lumber situation, in spite of certain irregularities, continues to show some improvement from week to week. The trend of affairs is in the right direction and a larger volume of business is being offered with prices highly competitive. More inquiries are also being received as the season advances.

There are certain features which are more pertinent to the softwood market than to the hardwood. The extensive housebuilding campaign, which has been going on in various cities and larger towns, has brought forth a keen call for hemlock, white pine, yellow pine, fir, chestnut trim andhardwood flooring, but the general class of dwellings has not been such as to call forth the higher grades of hardwood; neither are there being erected many large office structures or industrial buildings that require in any large quantities the costlier woods for interior and exterior trim. This, along with a slackened industrial activity, has caused the hardwood lumber market to remain much quieter than the softwood situation. While a number of firms have contracts for bank and office buildings, there is not nearly as much going on in this line as two years ago.

Furniture factories are still quiet; phonograph plants, owing to the competition for radiophones, are not by any means busy, neither are agricultural implement factories, as farmers are not disposed to purchase any new equipment owing to the rather poor crops of last year and the low price they have been receiving for their produce and livestock. What sales are being made, are principally to the automobile plants some of which are rushed; in fact several concerns have had a record production and are buying the upper qualities of thick birch, maple and ash. Not a few Toronto wholesalers have sold considerable quantities of native hardwoods in Detroit and Michigan during the last few weeks but the prices have been rather low.

There is an abundance of No. 2 and 3 common in all kinds of hardwoods, which can scarcely be given away at the present time. All buyers are clamoring for the better grades and do not want to take the bitter with the sweet, so to speak.

Some export business is being done in end dried white maple and winter-sawn basswood. A number of carloads have gone forth recently to the Old Country, these woods being used principally in the construction of pianos. Manufacturers and distributors of hardwoods are still looking forward to a reduction in freight rates and believe that as soon as rail transportation shows a drop, there may be a corresponding decrease in ocean carrying charges. Although the latter were reduced some time ago, they are still far from being low enough to enable Canadian firms to compete with the timber merchants of the Scandinavian countries.

Manufacturers of hardwood stocks are still asking high prices, and a number of wholesalers refuse to buy, claiming that manufacturers are asking more than the wholesalers themselves can get for what they have on hand. Some dealers declare that certain lines of hardwood are going to be very scarce before many weeks elapse, and that native woods in certain grades and thicknesses will be practically unobtainable. One wholesaler stated recently that there would be no dry birch 5/4 and thicker in 1sts and 2nds and selects on the market within a few weeks, and a hardwood flooring manufacturer asserted that maple in No. 1 common and better would be exceptionally rare. Unless some new supplies are forthcoming, prices he said were liable to advance considerably, and no one desired a runaway market.

Imported Woods

Reports emanating from the different American hardwood-producing centres seem to indicate that the last few weeks have witnessed a marked strengthening in the demand for various items of American hardwoods. This is particularly true in the southern producing areas where flood conditions have reduced the output to 25% of normal, and where owing to the severity of the floods, it is freely predicted that in many plants production cannot be resumed for three to four months. These conditions are becoming more fully realized by the consuming interests, with the result that wood users are checking their stocks and requirements closely, paying particular attention to their needs in southern hardwoods. There has not been any startling change in prices although the better grades are showing a tendency to advance. The demand for what might be termed "furniture woods," including fancy veneers, is light. This condition is attributed partly to the midsummer lull which usually hits the furniture trade about this season, and to the influence and proximity of the midsummer markets. Should a satisfactory volume of business result from the furniture exhibits at Chicago, Grand Rapids and other manufacturing centres, it will mean a strengthing demand for hardwoods on the part of furniture makers. The distress stocks, which were thrown on the market on account of flood conditions, have been practically all absorbed. This is expected to have an influence on value in the northern markets. With the exception of furniture manufacturers, other industries using hardwoods of different kinds are showing an eagerness to cover for immediate requirements, some going to the length of placing orders for future deliveries. This may be taken as an indication of the fact that many wood users believe that higher prices are imminent. Another fact that points to the same conclusion is that with the idea of holding them for the better prices which they believe will prevail in the near future. If this tendency becomes general, it will have the effect of forcing prices upward, for with decreased offerings and an increased demand, higher values are inevitable. Summing up the situation, it would appear as if the volume of lumber business being transacted to-day is greater than that experienced at this time last year.

Catalog of Kiln and Yard Equipment

A unique catalogue in the shape of a file folder is being distributed by the National Dry Kiln Co., Indianapolis, Ind. This covers their line of dry kiln trucks, transfer cars and yard equipment of various types. The book is profusely illustrated with engravings showing the various types of truck and yard equipment which are manufactured by this company. When placed in the office file it will serve as a ready reference for anything pertaining to kiln trucks and similar equipment.

News of the Trade

The woodworking plant, dry sheds and storage sheds of Henry Swim, Doaktown, N. B., were recently damaged by fire with an estimated loss of $20,000.

The mill and factory of the General Lumber Co., Sherbrooke, Que., was recently damaged by fire. The loss is estimated at $35,000.

The Mengel Co., of Louisville, Ky., manufacturers of mahogany lumber and veneers, have acquired the plant of the J. S. Otis Mahogany Co., New Orleans. This will enable the Mengel Co. to improve the service they are rendering their clients, if that is possible. When taking over this plant they contracted to saw all the logs of the J. S. Otis Mahogany Co., but outside of this there is no connection between the two organizations.

The new factory of the Cranbrook Sash and Door Co., which has been erected in the city of Cranbrook, B. C. will be started up this summer, it is stated. Plant which was purchased from a mill at Golden has been brought down and properly placed in the new building, and shafting all lined up. Electric power will be used, satisfactory arrangements having been made with the city of Cranbrook. The main power unit will be of about a hundred horse power, but there has already been a smaller motor attached to a sorting table and a good deal of the cut from their mill at Kitchener has been brought in and stacked. Work has almost been completed in preparation for the electrical installation and further equipment for their plant is now reported on the way from the east. Their new factory has been erected on the site of the building destroyed by fire some years ago, but has been enlarged and put all under one roof.

R. S. Gourlay, of Gourlay, Winter & Leeming, Toronto, piano manufacturers, returned from Vancouver rrecently. It will be remembered that Mr. Gourlay was taken seriously ill some months ago while on a trip to the Coast and was forced to remain in Vancouver for fifteen weeks. His many friends will be glad to learn of his recovery.

Gill & Fortune, Lumber Co., Limited, Trenton, Ont., was recently incorporated with a capital of $3,000,000 to conduct a general lumber business manufacturing and dealing in all kinds of wood products. Two of the incorporators are W. H. Gill and O. E. Fortune, lumbermen, both of Trenton.

The saw and planing mill of O. P. Moxley, Dorchester, Ont., was given a close call by fire that started in one of the lumber piles. Quick work by a bucket brigade supplemented by a tower tank in the yards extinguished what might otherwise have been a very serious fire.

The ratepayers of Harriston, Ont., recently defeated a by-law to grant certain concessions and other inducements to the True Set Wheel Co., who contemplated opening a factory in that town.

The Ruddy Mfg. Co., Limited, Brantford, Ont., who recently took over the business formerly conducted by Ham Bros., are installing a battery of three 11-car Sidman lumber curing kilns. These kilns will be of concrete construction.

The new plant of the Milverton Furniture Co., Milverton, Ont., is about complete. They are working now on their battery of Sidman lumber curing kilns. This plant will be operated in connection with the B. & N. Planing Mill Co., an associate company.

Total fire losses in Ontario in the last four years have amounted to more than $50,000,000, according to statistics adduced from the records of the fire marshal. The cause of conflagrations causing almost a third of the total damage is unkown.

J. S. Boyd, contractor, 245 Jamieson Ave, E. Kildonan, Manitoba, has erected a wood working shop, to manufacture window and door frames and contemplates installing a table saw, and 5 h.p. motor.

A. Fridman, and J. Driben, have taken over premises at 12 Albert Street, Winnipeg, to manufacture store fixtures, and general cabinet work. Both Mr. Fridman and Mr. Driben were previously employed with the Meletone Talking Machine Co. Ltd., Winnipeg, for a period of five years. The trading name will be The General Cabinet Makers.

W. T. Cole, who for the past ten years has been sales manager of Seaman, Kent Co,. Limited, Toronto has resigned his position and in company with W. C. Gardiner, who lately disposed of his interest in the Builders' Moulding Co., Toronto, and others, will embark in the manufacture of hardwood flooring of all kinds. The new organization which will be incorporated, has taken over the old K. & S. rubber plant on Oak St., Weston. The property covers some five acres. The latest equipment will be installed and the firm will produce oak, maple, birch and beech flooring exclusively.

The planing mill of the Hocken Lumber Co., Limited, at West River, Ont., was recently destroyed by fire which broke out from some unknown cause while the plant was in operation. The mill was well equipped and the loss will be about $15,000., which is partly covered by insurance. A strong wind was blowing at the time but, fortunately, the excellent work of the men and the efficacy of the fire protection system of the company saved the adjoining piles, and the sawmill, which is about three hundred yards away. The Hocken Lumber Co., will rebuild their planing mill in the near future.

Myers Lumber & Mfg. Co., recently moved their offices from 15 Toronto St., Toronto, to the new office building just completed at their plant, corner of Spadina Road & Eglinton Ave, This new structure provides a number of private offices and a large general office. The plant of this company has been completed and is in operation.

Lake Temiskaming Boat Co., Limited, Haileybury, Ont., have been granted a provincial charter to manufacture and deal in all kinds of boats. Capital $40,000. A. L. Herbert and Edward Bucknail, both of Haileybury are two of the incorporators.

The Streetsville Lumber Co., Inc., who some time ago took over the plant of the Harris Wood Products Co., of Streetsville have opened up a retail lumber yard in that place. The company, which is under the management of Thomas Wedgewood, has recently erected a two storey frame building 40 x 108 in which doors, sash and other lines will be manufactured. The Streetsville Lumber Co., will make a specialty of turning out garage doors on a large scale. They also operate a planing mill and are carrying the usual lines of lumber, dimension, lath, shingles, posts, etc.

R. J. McKenzie, of Fredericton, N. B. was recently appointed head of mechanical subjects at the Carlton County Vocational School at Woodstock, N. B. Mr. McKenzie is succeeding Mr. Heckbert who resigned to go into the furniture manufacturing business being organized at Woodstock, N. B.

Peerless Box Co., Limited, Ottawa, have been granted a federal charter with a capital of $50,000 to manufacture and market all kinds of wooden boxes and cooperage stock. Two of the incorporators are M. H. McVeity and Dr. D. W. Wallace, both of Ottawa.

The Massey-Harris Co., Limited, Toronto, Ont., are planning on erecting a $250,000 plant at Pine Bluff, Ark., to manufacture stock for farming implements. This company have large holdings of timber in that territory, sufficient, it is estimated, to last for twenty-five years.

Canadian Wood Cement Co., Inc., Acton Vale, Que., was recenty incorporated to take over the business of Arthur Pierre Beaupre and to manufacture and market cements and glue for use in the woodworking industry. Capital $20,000. A. P. Beaupre and Victor Martineau, both of Montreal, are two of the incorporators.

Chas. Pennington, secretary of the Valley City Seating Co., Limited, Dundas, Ont., recently delivered an address at a Board of Trade luncheon, in Dundas, in which he outlined the growth of that firm and described some of the lines manufactured. This company is supposed to have made the first circular church pews to be produced in Canada. This was about thirty years ago. The lines manufactured include furniture for lodges, churches, assembly halls, wood carving of various kinds and other forms of woodwork. These products have been widely distributed, shipments being made to all parts of Canada, and in addition, orders have been received from Newfoundland, South Africa, United States and even Jerusalem.

"The Stuff That Counts"

The test of a man is the fight he makes;
The grit that he daily shows;
The way he stands on his feet and takes
Fate's numerous bumps and blows.
A Coward can smile when there's naught to fear;
When nothing his progress bars;
But it takes a man to stand up and cheer
While some other fellow stars.
It isn't victory, after all,
But the fight that a brother makes;
The man who, driven against the wall,
Still stands up erect and takes
The blows of fate with his head held high —
Bleeding, and bruised and pale—
Is the man who'll win in the by and by,
For he isn't afraid to fail.
It's the bumps you get, and the jolts you get,
And the shocks that your courage stands;
The hours of sorrow and vain regrets;
The prize that escapes your hands;
That tests your mettle and prove your worth,
It isn't the blows you deal,
That show if your stuff is real,
But the blows you take on the good old earth,

Public Roads Bureau Gets $483,320 by New Act

U. S. Congress has finally passed and the President has approved the appropriation bill for the Department of Agriculture for the new fiscal year beginning July 1. For the Bureau of Public Roads the bill makes available $483,320, of which $367,120 is for various investigations and $116,200 for administration.

The appropriations include: $66,800 for investigations of road management and highway construction; $77,060 for investigation of best methods of road making; $175,000 for investigation of chemical and physical character of road material; and $15,000 for maintenance and repairs of experimental highways.

San Francisco Awards Contracts on Hetch Hetchy Power Units

The San Francisco Board of Public Works on April 28 awarded contracts for equipment to be used in the Moccasin Creek power plant on the Hetch Hetchy water-supply project. It is the present intention to sell power from this plant to one of the large power companies. Deliveries on the units for which contracts have just been awarded are limited by agreement to the period between April 15, 1923, and Aug. 31, 1923.

Contracts awarded were as follows: Pelton Water Wheel Co., four 25,000-h.p. double-overhung impulse units, $248,000; General Electric Co., four 20,000 kv.a. generators with exciters and one space exciter set $260,285; and the Coffin Valve Co., eight 36-in. valves, $37,586. The electrical units involve a departure from standard practice in that they have direct-connected over-hung exciters.

Building Operations Increase 32 Per Cent

Building operations in the United States increased 32 per cent. in 1921 over the previous year, according to a report of the department of labor. Wholesale cost of building materials, the report said decreased 38 per cent. in the same period and the average total cost of one family dwelling was $4,314 in 1920, compared with $3,925 in 1921.

Construction of one family dwellings increased 71 per cent. in 1921, two family dwellings 211 per cent. and multi-family houses (apartments and tenements) 201 per cent. Permits issued in 1921 were estimated to provide for 125 per cent. more families than those issued in1920.

The statistics were based on reports from 140 cities.

A Small Article

of Great Importance

Realizing the importance of efficient casters, we have made a specialty of this line and as proof of their quality we need only say that many of the foremost furniture manufacturers are using them exclusively.

By the way don't it seem logical that a Canadian-made caster should be the right one to use on Canadian-made furniture? Assuming of course, that it equals the standard of the imported article?

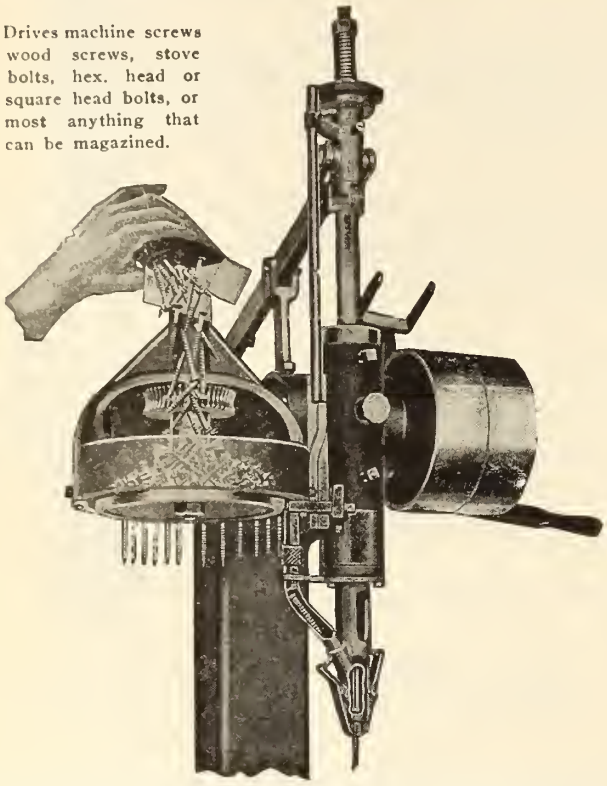
If you believe so too, just write us for samples and prices.

National Hardware Co., Limited

Orillia, Ontario

The Demand is for Lower Prices!

Drives machine screws wood screws, stove bolts, hex. head or square head bolts, or most anything that can be magazined.



Reynolds Automatic Screw Driving Machinery will help you meet the demand

Everywhere the manufacturer is faced with the problem of price reduction. How can he find the solution?

By cutting out every waste—of time, labor materials, etc.

Many manufacturers have installed Reynolds Screw Driving Machinery for this reason. It accomplishes the work better in one-third of the time.

Consequently they are able to meet the demand for lower prices and hasten the return to normal buying.

Are you interested? Then write us to-day for the full facts.

Send us dimensions over all of your work and gauge and length of screws driven so that we can determine the proper size and type machine to meet your requirements.

BOOKS FOR SALE

The following books are offered at special prices subject to previous sale:

"Machine Molder Practice," recently published by the Practical Books Co. 172 pages, 100 illustrations. Flexible leather binding. Price $3.00.

"The Utilisation of Wood-Waste," by Ernest Hubbard. Third English revised and enlarged edition, 236 pages, illustrated. Published in 1920 by Scott, Greenwood & Son. Price $2.00.

"Modern Practical Joinery,"—A comprehensive treatise on the practice of joiner's work by hand and machine. For the use of Workmen, Builders, Machinists and Architects. Containing a full description of drawing instruments and their use; tools, appliances and apparatus; methods and processes; joints and fastenings; woodworking machines; machine shop practice; preparation of work for machining; use of the steel square; house joinery, bank, office, church, museum, domestic and shop fittings, show cases, air-tight cases, splayed and shaped work; new materials and method, stairbuilding, foremen's work, fixing, and a description of nearly 150 woods suitable for joinery. Together with a comprehensive glossary and index. By George Ellis—fourth edition, extensively revised and much enlarged. With upwards of 1400 illustrations, including 20 double page and 41 photographic plates. Recently published by B. T. Batsford Limited, 570 pages. Price $12.50.

"The Kiln Drying of Lumber," a Practical and Theoretical Treatise, by Harry Donald Tiemann, M.E., M.F. Just published, by J. B. Lippincott Co. 316 pages, illustrated. Price $5.00.

Seasoning of Wood; A Treatise of the Natural and Artificial Processes Employed in the Preparation of Lumber for Manufacture, with Detailed Explanations of its Uses, Characteristics and Properties, by Joseph Wagner. Published by D. Van Nostrand Co., in 1917. 274 pages, illustrated. Price $3.00.

"Modern Practical Carpentry"—For the use of Workmen, Builders, Architects and Engineers. Containing a full description of the methods of constructing and erecting roofs, floors partitions, scaffolding, shoring, centering stands and stages, coffer dams, foundations, bridges, gates, tunnels excavations, woods and half timber houses and various structural details. Together with new and simple methods of finding the bevels in roofs, setting out domes, steeples, etc. An account of failures in construction, and the theory of trussing frames. Also including a concise treatise upon timber; notes on the woods used in carpentry; various tables; a glossary of terms and phrases connected with carpentry; and a chapter on the uses of the steel square. With about 1100 illustrations. By George Ellis—second edition revised. Recently published by B. T. Batsford Limited, 396 pages,—price $7.50.

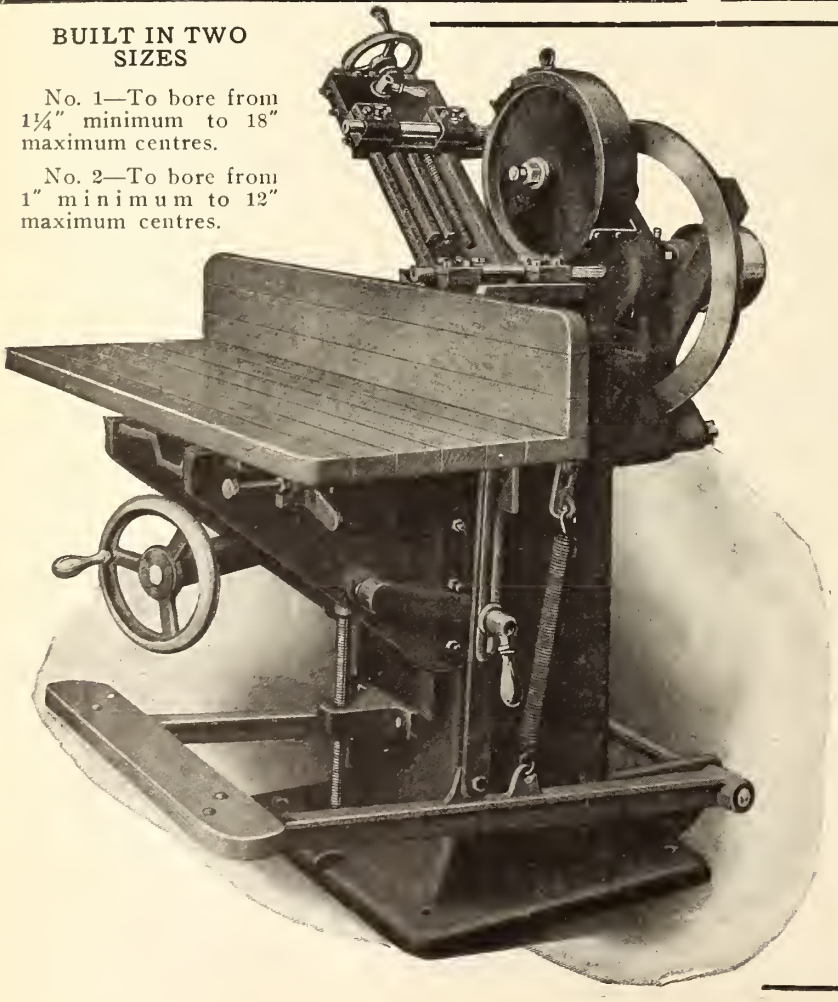
BUILT IN TWO SIZES

No. 1—To bore from 1¼" minimum to 18" maximum centres.

No. 2—To bore from 1" minimum to 12" maximum centres.



DOUBLE SPINDLE RADIAL BORING MACHINES

This machine is the standard of the furniture manufacturing world. It is finished with accuracy and combines versatility with never failing reliability.

The table is actuated with a central connecting rod, preventing the bureau drawer effect. The large intermediate gear is supported at any position by the large segment on the rear of the column. This rigid support eliminates the vibration set up by the action of the teeth and materially prolongs the life of the spindles.

A new Close Center Attachment has recently been perfected. It is universal and will bore two 5 16" holes anywhere in a circle of 1¼" with minimum centers of ½".

The new Quick Action Clamp attaches to the fence and eliminates the old stick.

Remember we can bore all of your holes at one time if you so desire

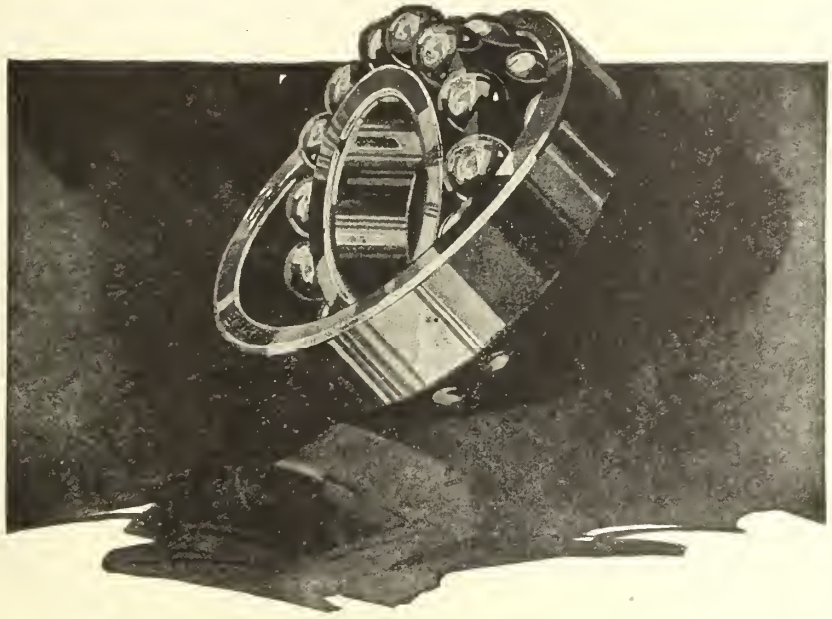
SKF



Wherever Misalignment is a Factor

THE operation of your machine will not be successful unless its bearings function in complete harmony with other parts. Deflections in the shaft, weaving in the frame and other causes may create severe stresses in all parts of the bearing, unless the latter has some inherent means to compensate for this misalignment.

The **SKF** marked self-aligning bearing operates on the same principle as the ball and socket joint and is therefore capable of taking care of the severest misalignment, Moreover the aligning action is positive, immediate and automatic.

The self-aligning bearing is a product of the Canadian **SKF** Co., Limited, and is sponsored by the **SKF** Industries. Its manufacture embodies all the minute care, precision and quality for which the mark **SKF** stands. The world-wide experience of this organization is put at your disposal, free of any obligation on your part.

Two Examples of Berkey & Gay Workmanship

Master Finishers at the Berkey & Gay Plant Use Carborundum Brand Garnet Paper and Cloth

THE name Berkey & Gay is always associated with the distinctively beautiful because in design, quality and workmanship Berkey & Gay furniture is the product of the artistry of master craftsmen.

In the creation of such furniture finish is an all-important factor. That is why many of the skilled sanders in this plant use Carborundum Brand Garnet Paper and Cloth—clean cutting, uniformly coated, flexible products that can be depended on to uphold the standards of good workmanship.

Carborundum Brand Garnet Products make good sanders better sanders.

The Carborundum Company

A good new Boiler is a real Dividend Maker

Especially when you can get the high quality of workmanship and the extra tested materials we employ (We have been at this business 36 years). As for prices—they are very inviting—in fact it doesn't pay any man who needs a Boiler to go without one from us at this time.

Morgan No. 6 Nailing Machine

MORGAN
NAILING MACHINES
Used in Nailing Wooden Toys

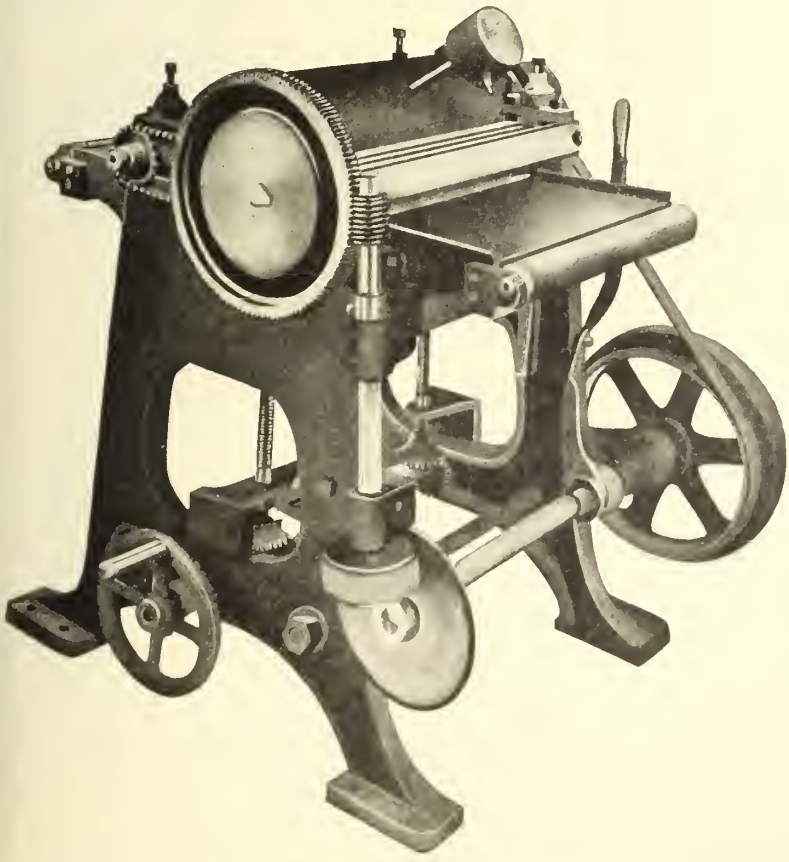
Many manufacturers of American Wooden Toys use our machines for driving 5/8" to 1 1/8" nails. Machines are adjustable in operation and can be adapted to any kind of nailing work.

If you are driving nails by hand, in making boxes, crates, toys, any woodenware articles, figure the cost. It is expensive.

Then send us samples of your work. Get an estimate of the cost of nailing on a Morgan Nailing Machine. Compare the figures. We'll leave the rest to your judgment.

Send us your nailing problems. We shall be pleased to give them our careful consideration and advise you regarding equipment for handling them. We invite your inquiry.

Morgan Machine Company
Rochester, N. Y.



The Elliot Bull Dog Planer

6" x 16"

The facts that the head is run by a worm gear; no pinions on the head and that the feed rolls are driven independent of the head excludes vibration. Hence—it planes smoother than any other Pony Planer made. Also it uses less power.

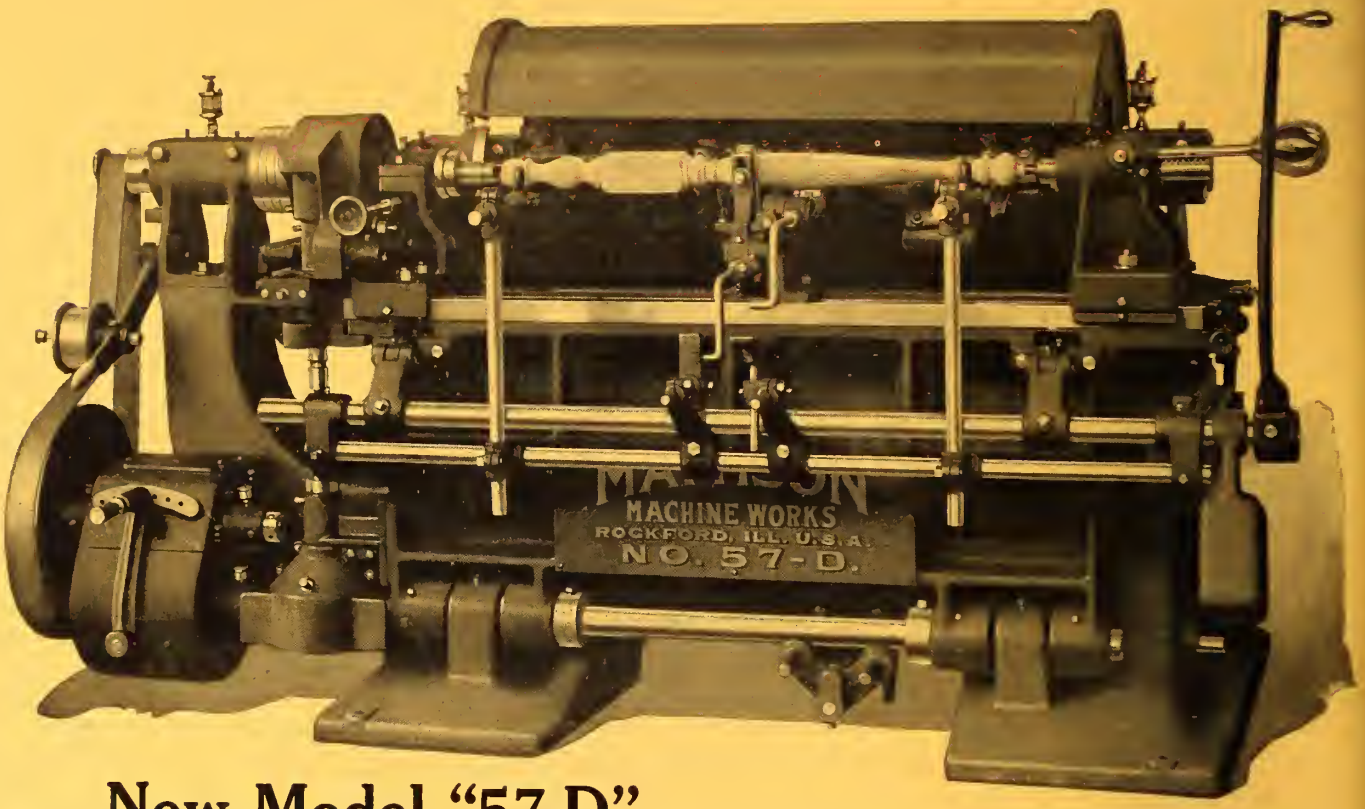
The Latest Improved Mattison Lathe

The Standard Machine Turner



New Model "57-D"

IN this New Model D Mattison Automatic Shaping Lathe are found the many improvements and refinements which twenty-five years' experience have shown to be desirable and necessary in a machine of this type.

It is not a radical departure in principle, nor is it a case of taking an old machine and patching on a new piece here, or cutting out something there. Yet it has been completely redesigned from the ground up. It has been made heavier where added weight is essential. Its operation has been made more convenient and faster. Attachments have been simplified to facilitate adjustments and to save time when changing. Gearing has been changed to eliminate readjusting when substituting different work-holding devices, thus insuring the gears against undue wear.

In a word, the developments and refinements on this new Model D Mattison Automatic Shaping Lathe leave nothing to be desired as to efficiency, operating convenience and simplicity. It is the culmination of twenty-five years' experience in continuously developing a principle proven right at the start.

Ask for bulletin describing new features.

The *Why* of Veneer Troubles

Do you know that—

veneer, unless redried, contains more moisture after it has passed through the glue spreader than ordinary air dried stock.

Veneer with this content of moisture is almost sure to go wrong—sooner or later. Why not make sure that your plywood when glued up, is as dry or dryer than the air—thus insuring yourself against trouble and perhaps loss?

A Perrin Veneer Re-Drier will safeguard you. Its operation is simple. The veneer is inserted between steam heated hot plates which extract the moisture from the wood fibres—from the centre first—and then from the surfaces. The opening and closing of the plates—known as the "breathing movement"—expels the excess moisture from the surface as it is drawn from the centre, allowing the shrinkage to take place naturally and without checking.

The sheets of veneer during this process are flattened out, making the stock easier to handle and simplifying jointing.

Veneer, re-dried by the Perrin Re-Drier will not check and warp or become seamed with hairlines, for it is drier than normal. By this process as much or more moisture is taken out as is added by the glue spreader, consequently your re-dried stock when applied contains approximately 8% moisture.

We can supply a machine with a suitable number and sized plates for your requirements.

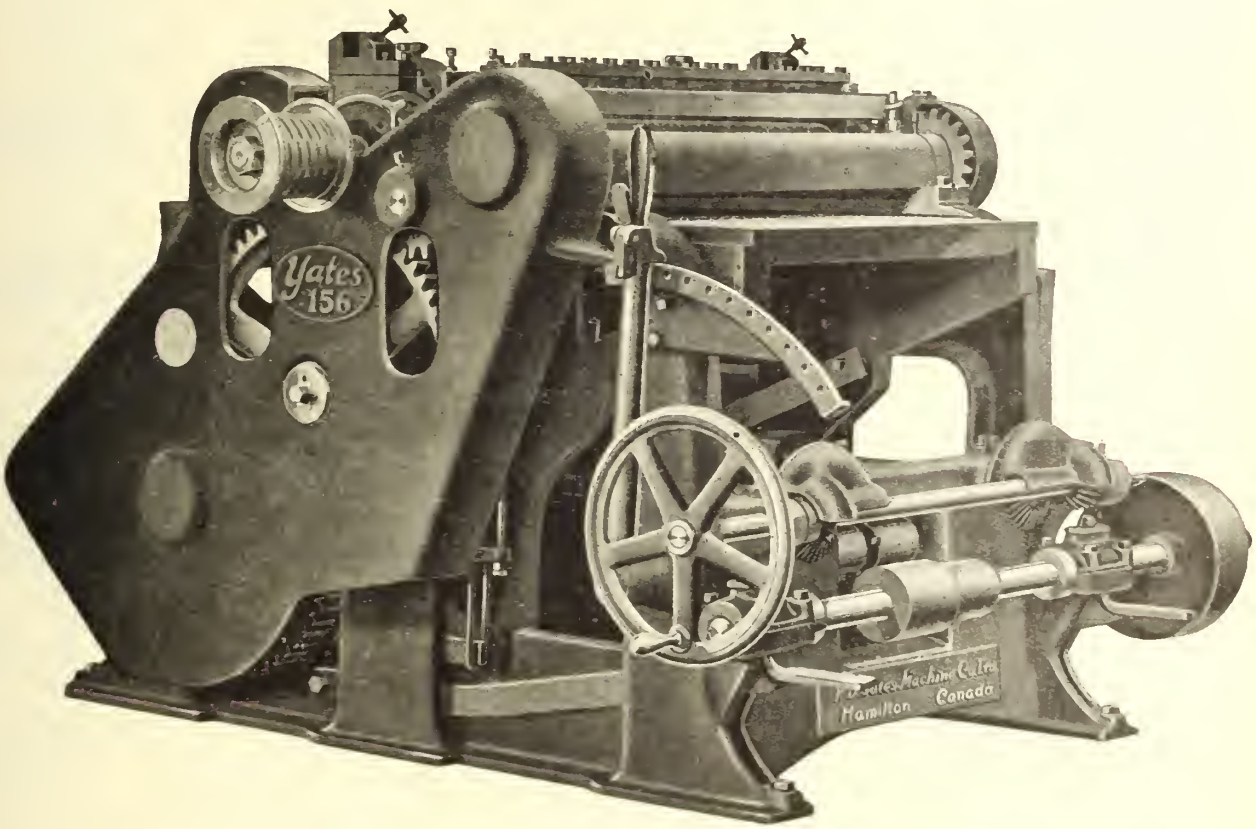
BALL BEARING

SINGLE SURFACER



The above machine is our New Type Ball Bearing Single Cabinet Surfacer. The Cutter head runs in journals fitted with SKF ball bearings. When machine is equipped with round cutter head, thin knives, sectional roll and chipbreaker, it makes the ideal single surfacer, that will give you the finest quality of finish.

By using the sectional roll, two or more pieces of unequal thickness may be fed into the machine at the same time. The 156 is built in three sizes, 27, 30 and 36 inches wide, takes stock up to 6 inches thick and will efficiently dress stock as thin as $\frac{1}{8}$ inch. Stock can be run thru as short as 6 inches.

Drop us a line for your copy of illustrated circular which explains this machine fully.

Cut Gear Specialists

CUT GEARS

Let us handle your gear requirements

Gear Data For Your Note Book

Cut this out,—more coming later

DEFINITIONS AND RULES FOR GEARS
from The HAMILTON GEAR & MACHINE Co., Toronto

Diametral pitch (D.P.) of a gear is the number of teeth per inch of pitch diameter.

Circular pitch (C.P.) of a gear is the distance from centre to centre of teeth measured along the pitch circle.

Circular pitch equals 3.1416 divided by Diametral pitch.

Thickness of tooth at pitch line is half the circular pitch, or equals 1.5708 divided by the D.P.

Addendum is the distance from pitch circle to outside of gear.

Dedendum is the distance from pitch circle to bottom of tooth.

Clearance is dedendum minus addendum, or equals 0.157 divided by the D.P., equals 1-10 thickness of tooth.

If **outside diameter** (O.D.) of a spur gear is given to find diametral pitch, add two (2) to a number of teeth and divide by the O.D. in inches. Reverse process to find O. D.

Pitch diameter equals the number of teeth (T) divided by the Diametral pitch, or it equals the number of teeth multiplied by the circular pitch and then divided by 3.1416.

Distance between centres of two gears is half the sum of their pitch diameters.

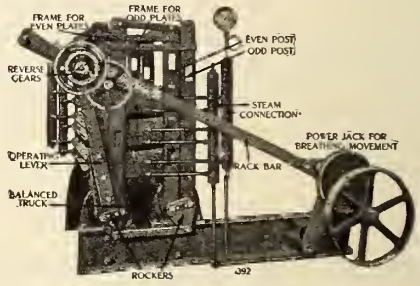
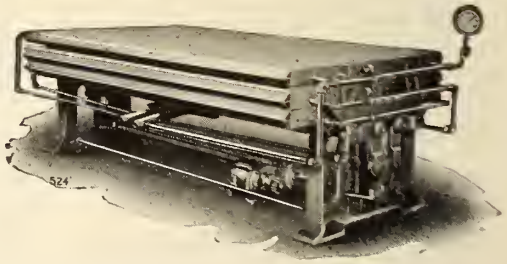
MESCO

It Pays to Install a "Merit" Re-drier



Bulletin No. 70-C.W.

Re-drying was not practiced to any extent 15 years ago when the "Merit" re-drier made its appearance on the market. Today very few glue rooms take a chance on veneer that has not been re-dried under hot plates and very few plants using veneer have neglected to install a "Merit" re-drier. This machine flattens the veneer and makes it absolutely bone dry. It takes very little steam and is operated by a 2 h.p. motor. It saves glue, simplifies taping and jointing and insures success in the finished product. It is made in several sizes of plate and starting with 4 plates, a machine can later be expanded to 12 or 16 plates.



The Three Plate Re-drier

Veneer Lathes, Clippers, Driers and Re-driers

Plywood and Panel Machinery

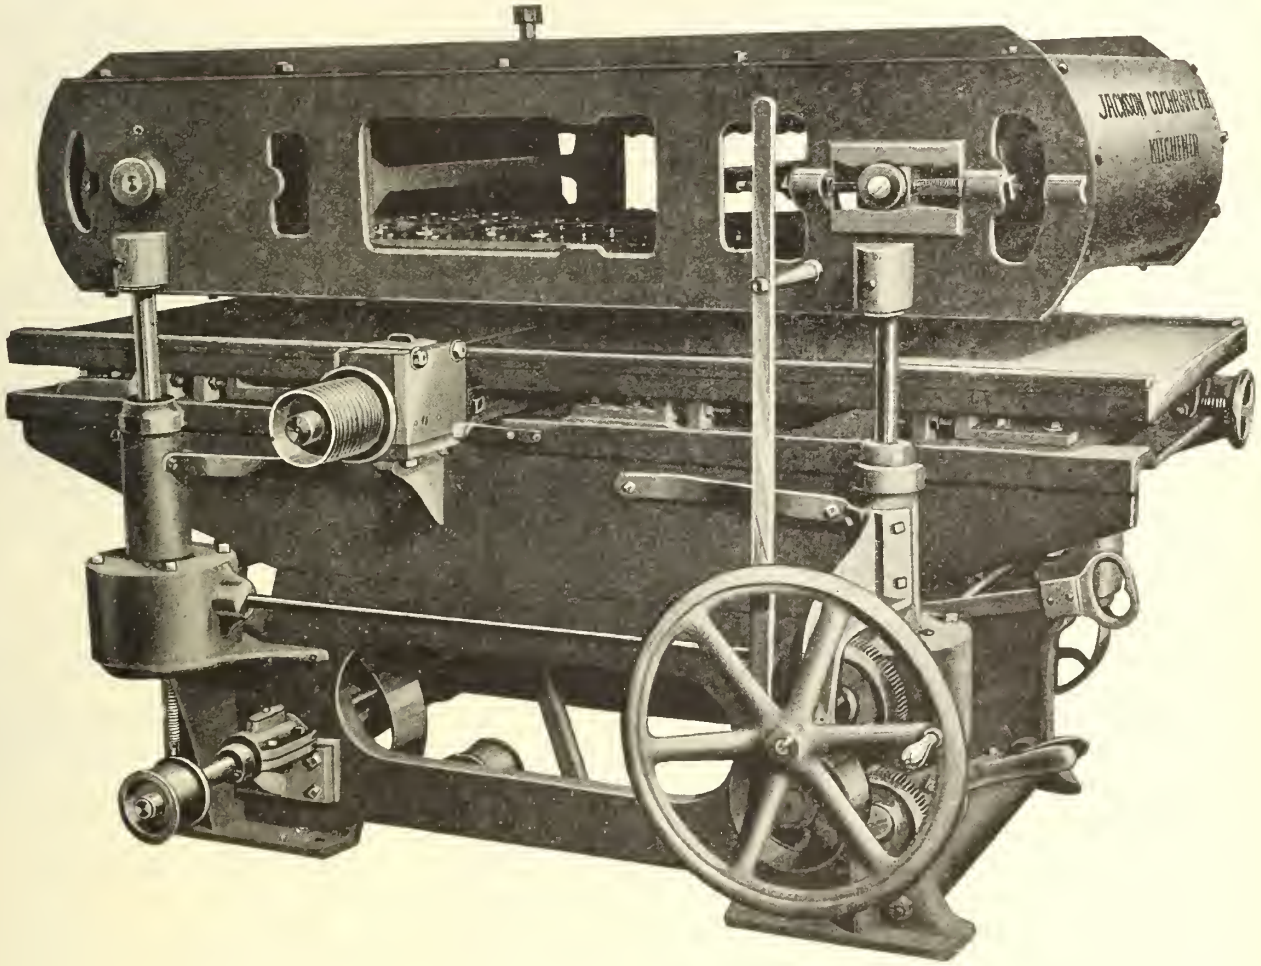
Basket and Crate Machinery

MERIT

"The Best Equipment Possible for the Work it is Intended to Do"

—*Says Panels, Limited*

of Southampton, Ont.



This machine not only increases production while lowering operating costs but entirely eliminates the dangers to which the operator of the old style buzz planer was subjected.

Just consider these facts:

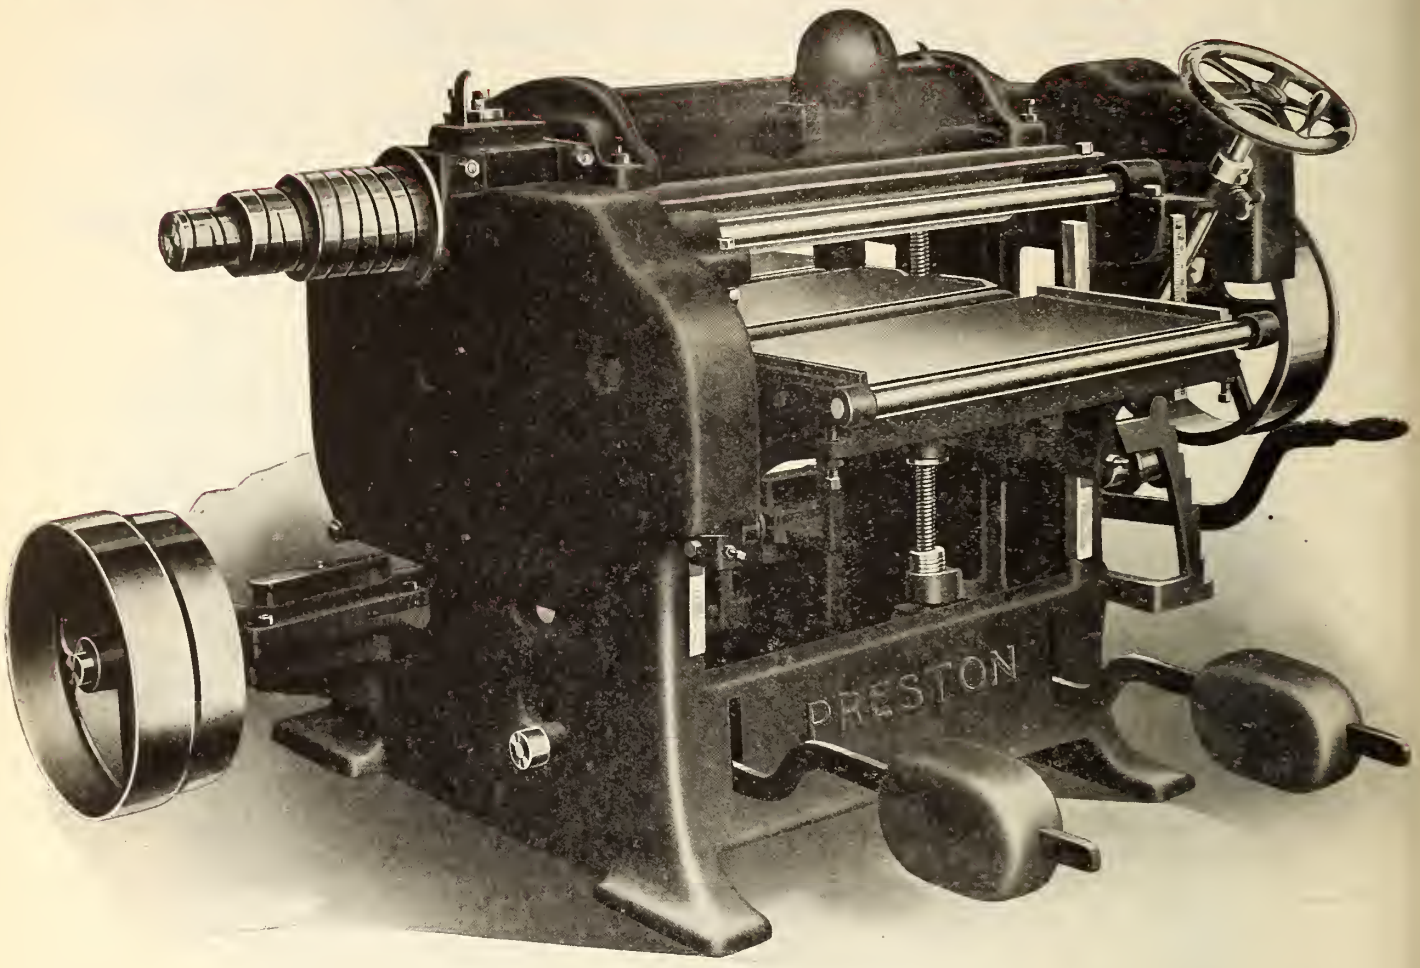
It handles stock of any dimension, hard or soft, at four times the speed of the old method; occupies but one fourth the space required by four hand jointers; requires but one-fifth of the sharpening of the knives as the hand fed jointer and is easily operated by two boys.

These facts we shall be glad to prove to anyone interested in such a machine.

Jackson, Cochrane & Company

KITCHENER - CANADA

No. 121 "Preston" Heavy Pony Planer



Cut Showing Standard Machine (note Guards)

This is our No. 121 Planer of improved design as now built

Planes 20″ and 24″ wide. 8″ thick

Features:—

1. Built with Straight Rolls (Standard Machine)
   or Divided Roll
   or Sectional Roll and Sectional Chipbreaker
2. Built with Square Cylinder with 2 carbon knives (Standard Machine)
   or Round Cylinder with 4 High Speed Knives.
3. Equipped with Whitney Type Babbitt Bearings (Standard Machine)
   or Specially selected SKF Ball Bearings.
4. Equipped with Stockbridge Electric Knife Grinder if desired, at extra cost.

Cylinder driven from one or both ends.

Every known improvement is embodied in this "Preston" Planer and in it we have produced a small planer which in quality and quantity of work produced will compete successfully with larger and higher priced machines

The Preston Woodworking

PRESTON,

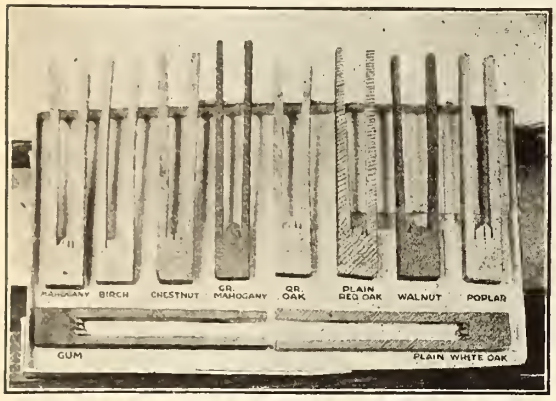
Specialists in Ball Bearing Woodworking Machinery

Make these savings at your plant right away!



Globe-Wernicke Co., did this—9 different problems handled effectively—a box of test pieces all cut in one day showing splendid results. Nine different problems solved with their 16 Standard Dry Kilns. Get our literature on making these tests.

STOP MERELY TRYING—OTHERS DO IT!

It CAN be done; this shows an example. And one kiln of oak saved, or even one foot more on each board you dry—figure that out! Get straight lumber, free from case hardening. If your old klins won't do it as they stand, give us a description of them and have our expert immediately give them the "once over"—it's often only a matter of building in to them our valuable and effective features. And if you need new kilns, get ALL of our features. They produce results—it's time to stop wishing—rip into the trouble, we are helping the leaders—ask us what it will take to put you on this low-cost drying basis. Put your name on this—mail it back to us. Address us at 1542 McCarty Street, Indianapolis, Ind.

The Standard Dry Kiln Co.

Drudgery Demoralizes Men

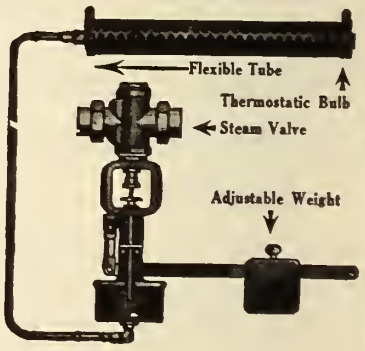
Put your men on jobs they like and you will go far toward solving the labor problem. For example, take the men off the drudgery of watching thermometers and turning steam valves.

Powers Heat Regulators

With these automatic guardians on the job, more men are released for work that is directly productive. Besides, you save fuel and materials and standardize your product. Powers Regulation is a necessity in most plants right now. Probably yours is no exception.

Here's a Fair Test—Try one for thirty days at our risk.

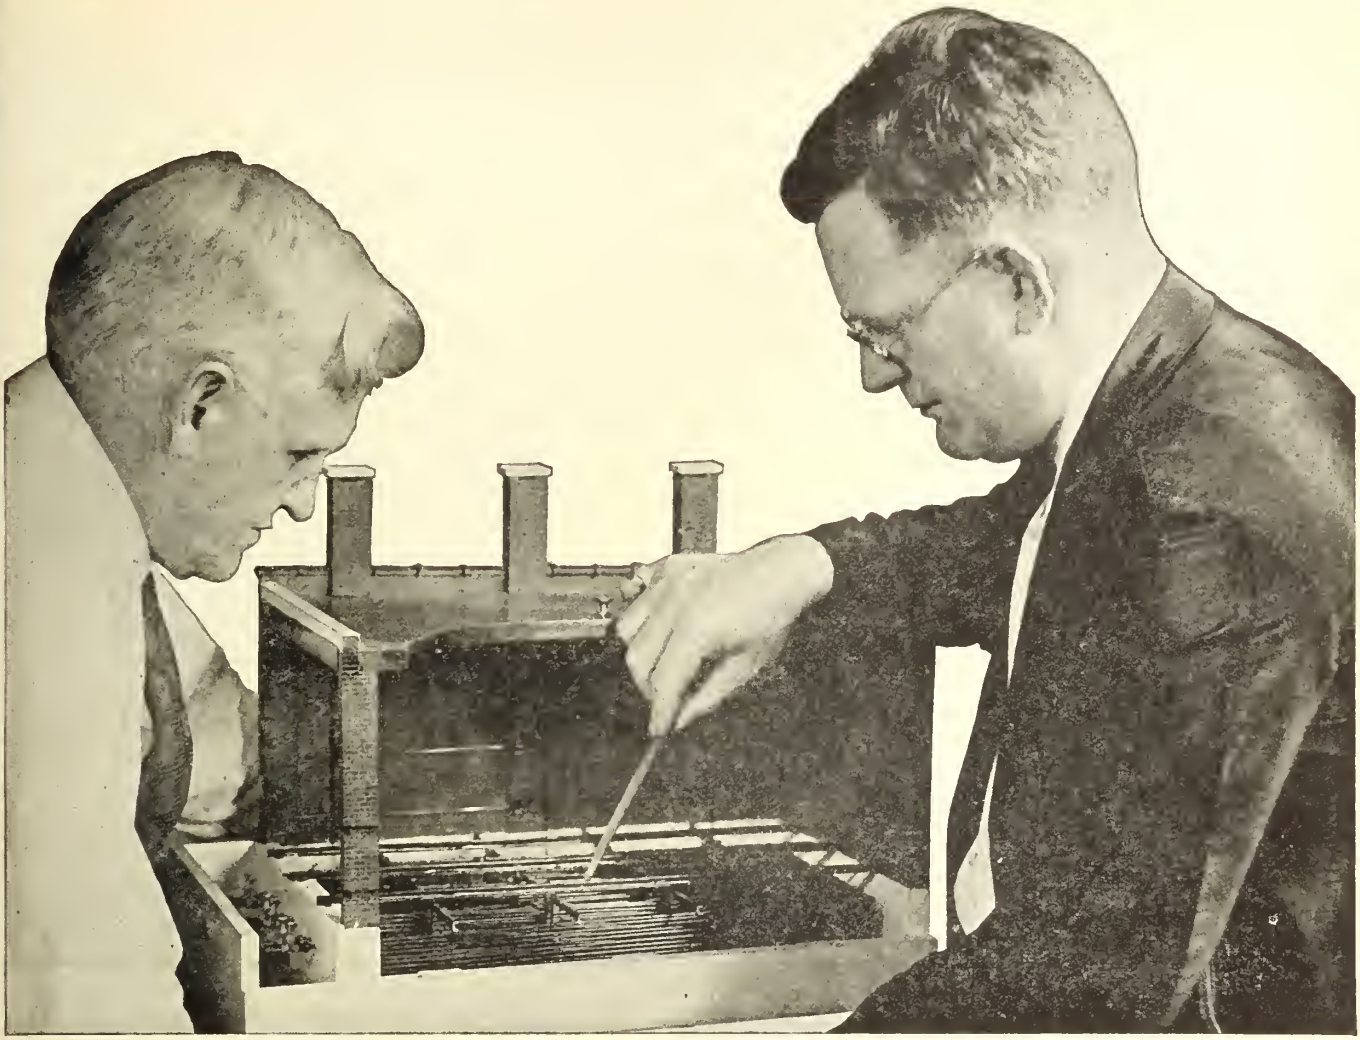
The Canadian POWERS REGULATOR Co. Ltd.
Specialists in Automatic Heat Control
82 CHESTNUT ST., TORONTO ONT.



The Powers Regulator No. 15

For control of air temperatures. The thermostatic bulb is so constructed that it may be placed at any point and in any position in the room to be controlled, and connected with the steam valve by a flexible tube, of any required length. It is very sensitive and reliable. Self-contained and entirely automatic. Particularly adapted to control temperatures in dry kilns, ovens, varnish and dry rooms, etc. Write for bulletin 138.

[1775]



Ira A. Minnick, President of The National Dry Kiln Company, is using his freckled right hand to show exactly how the National spraying system provides for the expansion of steam and a reduction of velocity so that the moisture from the spray will enter the room in the form of vapor rather than at the high velocity of the steam jet.

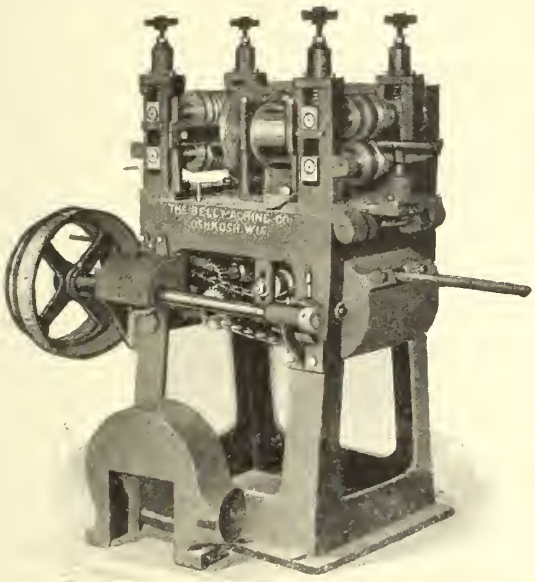
Make Your Own Dowels With the "BELL" Machines

The Fastest and Most Practical Equipment For the Purpose



Adjustable Rod and Dowel Machine

The fastest dowel machine in the world.

Constructed to withstand the heavy and constant strain to which this type of machine is subjected.

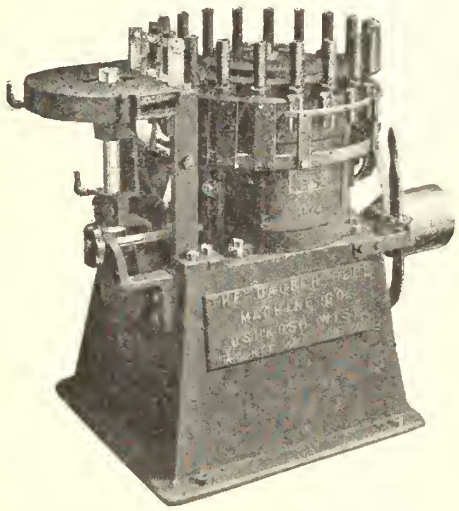
Equipped with a universal four-knife cutter head adjustable to turn rods of all diameters from ¼" to 2" in either plain, spiral groove, longitudinal groove, or imitation reed wind. Special machine for turning rods of larger size.

Cutter-head mandrel is mounted at each end in ball-bearings of the highest grade.

Out-going feed rolls have combination of grooves so that many sizes can be made without changing feed rolls. The in-going feed rolls are adjustable for all sizes of squares.

Will work stock as short as 4½ inches.

Furnished with countershaft or motor drive.



Dowel Cutting Off and Pointing Machine

This machine is for cutting off and pointing dowel pins from long rods.

It will cut and point dowel pins of all diameters up to ¾", and in any length up to 6 inches.

Capacity of this machine is from 300 to 400 pins a minute. Any boy can operate it.

All working parts are completely enclosed and thus protected from dust and dirt.

Absolutely no danger to operator.

The floor space required by this machine is only 22" x 36".

Tight and loose pulleys on machine.

Furnished with belt or motor drive.

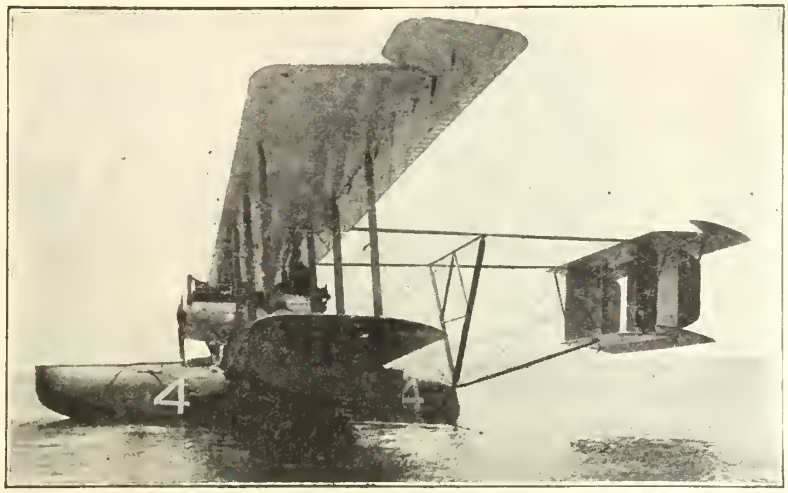
HART & LEFEBER, LTD.
Canadian Distributors, 38 Grey Nun, Montreal



The famous N.C.-4, first airship to fly the Atlantic, photographed in the harbor at Ponta Delgada, Azores, in May, 1919—just after her flight across the Ocean from Labrador.

MONITE
Waterproof
Glue

Made from casein, is a necessity in the construction of the modern hydro-aeroplane. MONITE WATERPROOF GLUE stood the test of trans-Atlantic flight—and is used by the Army and Navy to-day—because MONITE sticks.

Made Trans-Atlantic Flight Possible

The N.C.-4, flagship of Lieutenant Commander John Reed, U.S.N.—the modern Christopher Columbus who first flew the Atlantic—was built with **Waterproof Glue.**

The engine-bases of the N.C.-4, to which her three high-powered gas engines were bolted, could not be made of steel or aluminum, for metals crystallize too quickly under the terrific vibration of such motors. They were, therefore, made of wood about three inches thick, built up of 20 very thin layers of plywood with the grain of the wood well criss-crossed and all 20 layers solidly glued with Waterproof Glue.

Struts, braces, framework, fusilage and even the plywood hull planking, all glued with Waterproof Glue, withstood the terrific jarring of the engines, the wrenching and twisting of 100-mile-an-hour flying through ocean winds, the impact of alighting and the hammering waves of the open sea.

Monite waterproof Glue endured the extremes of temperature from the cold, foggy upper air of Labrador to the semi-tropical atmosphere of the Azores. It was proof against the drying action of ocean sun and against the soaking, smothering swirl of white water kicked up at "the getaway" and the drowning splash of the landing "dive."

The triumph of **Monite Waterproof Glue** in its crucial trans-Atlantic test needs no further evidence—the U.S. Navy today specifies Waterproof Glue for hydro-aeroplanes and also for its small boats.

Monite Waterproof Glue opens up new uses and new markets for glue-made products—for manufacturer and retailer. We will be glad to suggest what it can do for YOU.

Write us for a "vest-pocket" panel of MONITE for you to test by boiling, soaking, and baking. Find out that MONITE STICKS.

The Canadian Appraisal Co. Limited

The Pioneer Appraisal Organization of Canada

Established 1905

"An adjustment of fire insurance in accordance with existing values is a universal necessity. Many people who now believe that they are properly covered against the fire risk are, in reality, inadequately covered. Morever, realization of these facts is by no means general."

The Chronicle

Over 85% of the appraisals made during the past fifteen years of Canadian manufacturing and industrial properties have been carried out by us, aggregating some 5.000. properties, and include over 250 lumber and woodworking plants.

Efemco Casters

Work well
Look well

There is double satisfaction found in merchandise that has great quality and at once is good looking.

It's the same with casters like **Efemco**. They work every time and all the time. They never bind or jam and always roll easily. At the same time they are good looking and add much to the piece that they equip.

The salesman is proud to say that the furniture in hand is fitted with **Efemco** Casters.

A kind for every use.

Standardized by 57 years of service.

Correct in Design

Reasonable in Price

For many years the European Masters of Decoration have developed ornamentation to a high degree. It is this high standard which they have set that we use as our guidance.

In offering you our services we do so with the knowledge that the final Result will not be a guess at what is correct, but rather the result of years of experience in decoration.

The two drops above are of our many new designs and are half size. Until our new catalog is issued write in for your requirements. Give us a general idea of what you require, it may be among our many new patterns.

We are always ready and glad to work from your suggestions.

Co-operation is the order of the day.

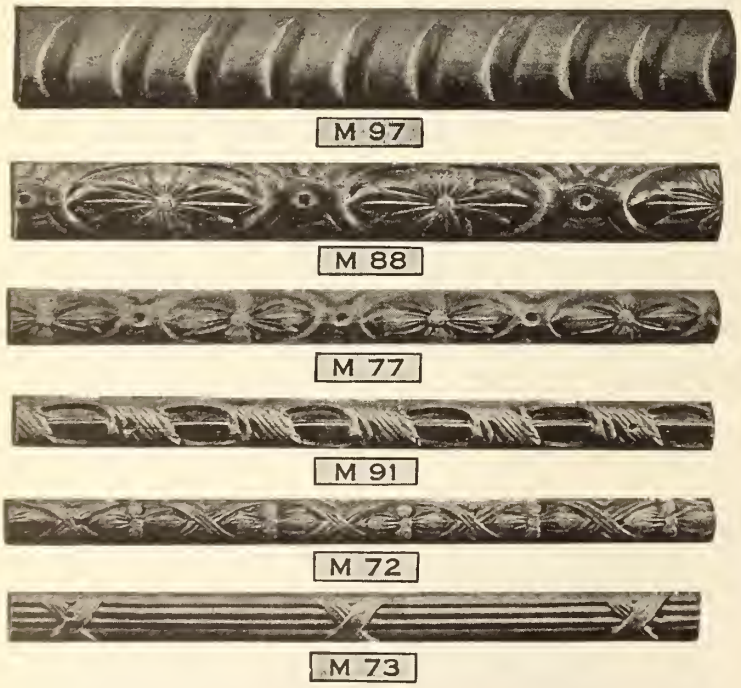
CARVED MOULDINGS, CARVINGS, CARVED LEGS

No. D-775 (Reduced One-Half)

No. D-763 (Reduced One-Half)

"KLISE" mouldings are carved, not pressed. Made in several hundred classic, period designs, in various sizes and shapes. Catalogue of legs and samples of mouldings sent on request. Send us your designs or samples of carvings for quotation.

KLISE MANUFACTURING COMPANY
Grand Rapids, Michigan



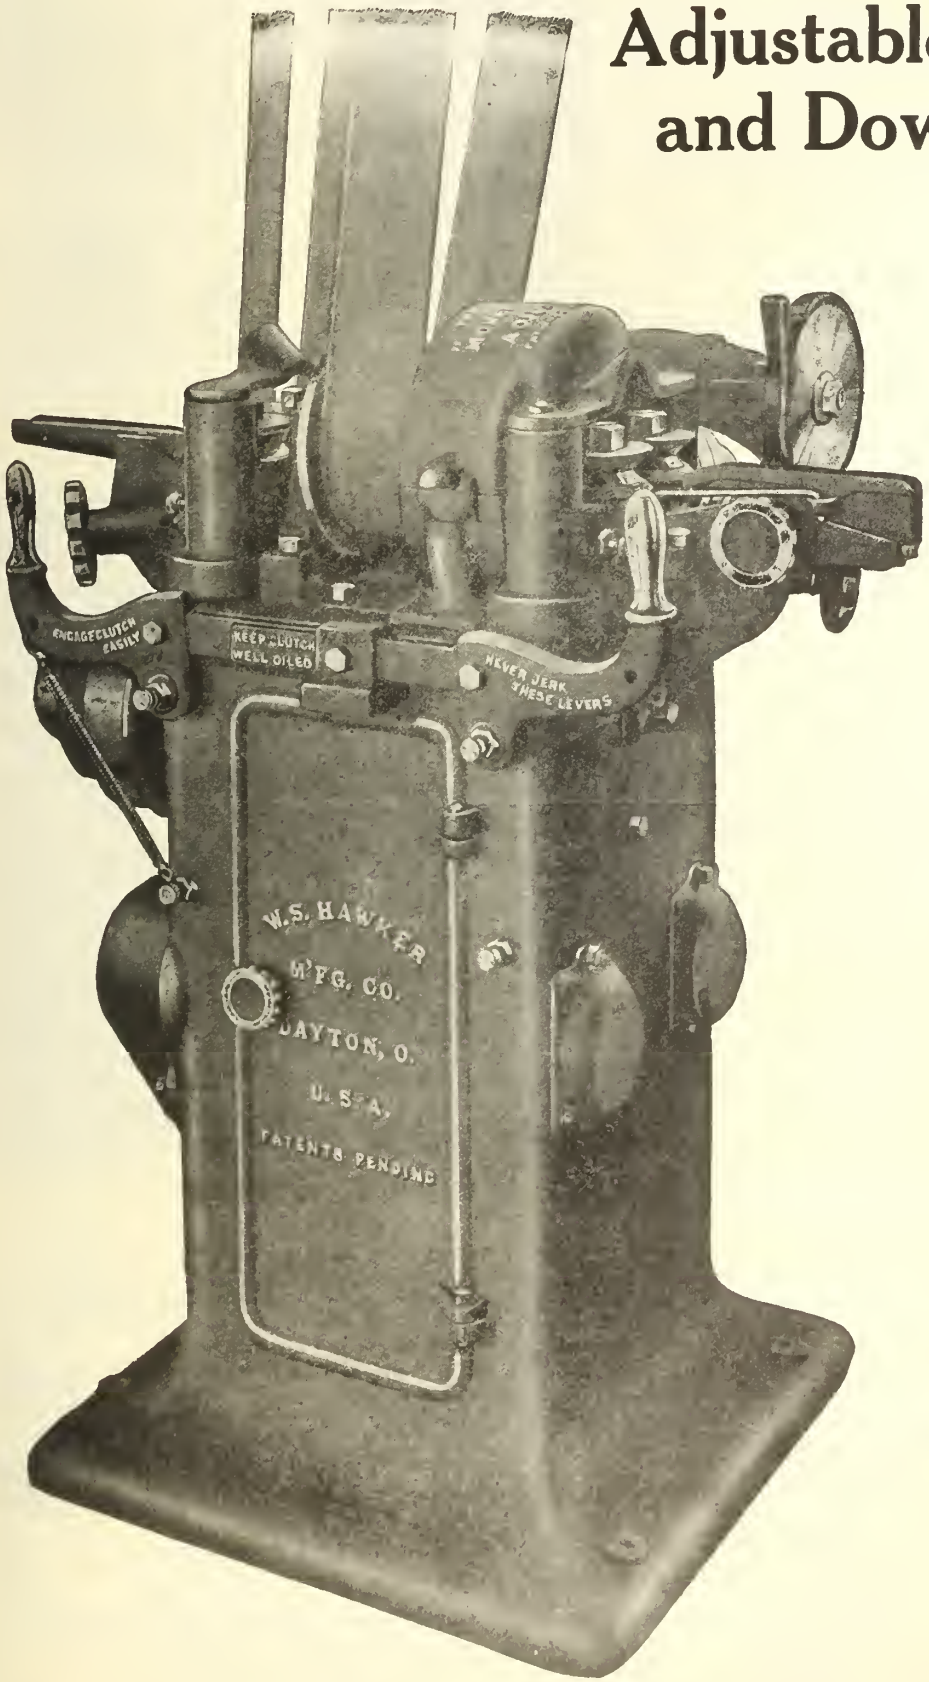
MOULDINGS We are making more Period Mouldings than ever before. Orders should be placed early to assure your supply when needed.

KNOBS The Period Knobs we placed on the market a few months ago are proving very popular. If you have not received samples ask for them now.

ROSETTES A new Period item to accompany the knobs.

Waddell Manufacturing Company
Coldbrook and Taylor, N. W. Grand Rapids, Mich.

The Money Maker— Adjustable Rod and Dowel Machine



Capacity 30,000 to 40,000 lineal ft. per ten hours on 7/8 or 15/16 mop or sweeper handle stock.
If you are using any dowel machine of less capacity, figure your daily losses in labor and business.
Write us what dowel sizes you turn, and whether hard or soft wood. Ask for our demonstration proposition to show you how to double your production of dowel stock at the same labor cost.

The machine that is sent under a guarantee to show you a gain of from 100 to 400 per cent before you buy it.
The improved dowel machine that 90 per cent of the largest and oldest machinery builders and dealers now endorse and recommend in preference to the solid chuck machines they themselves previously built.
One cutter head turns from ¼-in. to 2-in. diameter.
Turns hard or soft wood equally well.
Handles heavy, oversized squares.
No choking of the cutter head.
Smooth stock.
Accurate sizes.
Works stock as short as five inches.
Rolls automatically center variations in squares.
Machines built to turn from ⅛ to 6-in.
We want to hear from every user of a solid chuck dowel machine.
We can save you from one dollar out of every two, to four out of every five that the operation of solid chuck machines costs you.
Engagements for competitive test solicited.
Formal orders not solicited. All sales made after demonstration.

The only question is, are you willing to cut cost of your dowel turning to one-half or one-third of what it costs with any make of solid chuck machine?
Machine delivers the goods before you buy.
State conditions of stock closely
Special conditions require special equipment.

Using a Hundred Papers Where One Would Do Better

IF you wished to reach every electrical man in every town in Canada—engineers, dealers, designers, manufacturers, central station operators; you could do so by using a hundred odd local daily and weekly papers. But if you wished to reach these same men economically and at a time when they were thinking business—not golf and home—you would use just one publication and that would be the national publication:

Walnut?—Yes,—Good Walnut?—Yes!
Pickrel

Walnut's sheer beauty, strength, uniformity and permanence brought it in a few years to unquestioned supremacy in furniture construction. Dominance in furniture proves but the beginning. This surpassing merit is every day compelling increased use in new cabinet fields. Pickrel walnut veneers fill an important place in this wider development. A limitless selection of quality veneer logs, careful and skilled manufacture and a constant stock of five million to seven million feet of nicely assorted woods have given Pickrel walnut veneers a special significance. Buyers will appreciate the responsible, conscientious and experienced representation through which Pickrel veneers are offered at their respective plants. It assures the closest possible conformity to the individual requirements of each—meaning less cost in working and a better product.

A Thirty-Five Years' Unbroken Record of Fulfilling Sales Contracts Regardless of Market Changes

AT all times it is important that buyers of Southern Hardwoods look well into the **reliability** of the lumber manufacturers they deal with. It is doubly important in such times as these when the market is advancing. There are strong indications of further advances and buyers should protect themselves by placing their orders with concerns who can be relied upon to execute and fill their orders in an advancing market; who can also furnish stock fully up to grade under any condition.

The Chapman & Dewey Lumber Company has the reputation of never having failed to fulfill a sales contract regardless of the market. This is an unbroken record extending over 35 years.

MAHOGANY

Rarely are such stores of precious wood to be found as may be seen in our yards. Across the seas from tropic lands it comes. From thick jungles where the light of day but dimly penetrates and where tangled native paths make difficult the bringing out of timber. Here the black man labors, risking life from jungle dangers, that supplies will not diminish and your orders may be filled.

Twelve million feet per year is the capacity of OTIS mills. An adequate supply is always on hand for prompt shipment. Get our prices.

Otis Manufacturing Company

Peters Avenue and The River

Chicago Office: Room 208, 128 N. Wells Street

Specialty E C & S *Birch*

Canadian Birch allows full Expression of the Furniture Craftman's Art

It would be difficult indeed to imagine a more beautiful Chesterfield chair than the one shown above, bearing the stamp of one of our large American clients.

It is only logical that such beauty of design and skill of workmanship should command the finest materials—in this case Canadian Birch supplied by Edward Clark & Sons Limited.

As a matter of fact this same wood finds its way into much of the fine furniture manufactured both in Canada and "across the line."

A close, even texture, beautiful grain and economical cost undoubtedly account for its popularity.

We shall be only too pleased to send you prices and further details. Why not let us ship you a trial car?

Edward Clark & Sons Limited

Avoiding Credit Losses

The owner and manager of one of our largest woodworking establishments recently remarked that he was not opening any new accounts until the speculative element in the present building activity—this means in most cases the newer builders in the field—had had sufficient time to make good or go under. To put it another way he intends to play safe instead of carrying the load and taking the chances of those who have little or nothing to lose but who stand to make a good profit if they can turn their building at fair figures. His attitude is not only logical but shows sound business judgment. Later on when conditions in the building field have become a little more stabilized will be time enough to consider extending credit to new accountants.

Woodworkers have never given the attention to credits that the subject should receive and a result of granting unwise credits, of taking unnecessary chances and of not being able to collect what is justly due them, many are out of business who should have succeeded but for this oversight, whilst others are struggling along hampered by lack of capital and shortage of available funds when they should be on easy street. This is so generally known that it is a wonder we do not profit from our observations and experience.

Credit, it is said, is the foundation of our whole business structure; it is also the quicksand of our business graveyard, if handled unwisely. Why should a builder expect a woodworker to supply him with lumber and building material and then wait for his money until the building has been completed and sold? About the most logical reason which can be advanced is that it has been done, is being done and doubtless will be done.

That the building industry is looked upon in a different light is evidenced by the lien laws drafted to protect those who cater to the demands of this field. Regardless of the protection which may or may not be afforded by our machanics' and other lien laws it is questionable if there is any valid reason why credit terms should differ in this field. In other lines, even where the turnover is extremely large, short credit terms, thirty days, are allowed on approved accounts and those who cannot command a good rating are compelled to pay cash or go without. It would be a good thing, a step in the right direction, if some concerted action tending towards shorter, stricter, uniform credit terms were taken by those woodworkers who deal largely with the building industry.

Nor should this stop there, as those in other branches of the industry are not immune from credit losses. It is particularly unfortunate that in an effort to secure orders and keep things moving many woodworkers sacrifice profits and then take a chance on getting any of their money. In other words they gamble with credit as well as with money in their struggle for business. When it is not certain that the money will be forthcoming, when it is felt that a chance is being taken, it is then time to either call a halt, demand security or make a thorough investigation into the standing of the customer with a view to ascertaining exactly what the risk is.

The furniture industry is in the most favorable position, with regard to granting credits, of any branch of the woodworking field. Through their association they have developed a credit Bureau which has been raised to a high degree of efficiency. The result is that those who consult this bureau and follow its ratings are doing business with a minimum of loss. This is evidence to the fact that several of the larger furniture manufacturers, those doing a large volume of business, are not making any debts, while some others who think they know or who are willing to take a chance, are incurring losses running into thousands of dollars annually.

When some such source of information as the furniture manufacturers' credit bureau is not available it is well to ascertain all facts pertaining to credit customers, learn what their assets are, if they are clear or encumbered and best of all get a few references among those with whom they have been doing business and then investigate and see if they are slow or prompt to pay and if they are considered good risks. Profits are too uncertain in the woodworking field to give one much leeway to gamble with credits.

It seems to some men that it is impossible to set four counters on a block so that each will do its fair share of work. It can be done, but it requires careful adjustment of the cutters and a knowledge of how to sharpen them.

What About Reducing Your Costs?

Is Too Much Attention Being Given to Cost Recording to the Exclusion of Cost Reduction?—It is Essential Not Only that Costs be Known and Recorded but also that Every Attempt be Made to Keep Them Low—Functions of the Cost Accountant and Industrial Engineer Compared

By L. R. Wright*

Recent issues of the "Canadian Woodworker" have contained a wealth of good material dealing with cost accounting in the woodworking industry, outlining how cost data can be secured and recorded, and stressing the vital necessity for a greater interest in accurate costs. The need for wide spread cost knowledge is great. Undoubtedly vast sums of money are being lost in this industry each year, because of a lack of interest in cost work and cost records, or because there are many woodworkers who do not or will not realize the value of maintaining a cost system.

Without in any way detracting from the value of and necessity for cost work, a woodworking plant is not properly organized unless it has a cost system in operation. I would like to deal with another phase of management and organization, equally important or perhaps more important, the value of which is not so widely recognized, namely, industrial engineering. My intention is to compare these two phases of plant organization, show how both are vitally necessary for the highest degree of success, how each dovetails into the other and how one provides an ideal foundation for the other.

Industrial Engineering in Woodworking Plants

It was not so long ago, perhaps a little over a year, that the "Canadian Woodworker" and several other papers published an article dealing with engineering in the woodworking industry. This treatise outlined briefly some of the directions in which the specially trained industrial engineer could assist in improving methods, increasing production per man and per machine, eliminating waste or at least diverting it into more profitable channels, and reducing costs, all tending to raise the status of the woodworking industry and to place it on a plane commensurate with its greatness and age. At the time this article aroused a considerable amount of interest as there was a slight realization of the need for the services of specially trained engineers and a further realization of what could be accomplished if gone about in an intelligent and practical manner. Since then there has been a fuller realization of the need and value of the industrial engineer with a corresponding increase in the interest which is really being shown in this work and as a result industrial engineering has been and is being successfully carried out in many woodworking plants.

The Work of the Cost Accountant

To many, the cost accountant and the industrial engineer are closely allied. This may be due in part to the tendency of some few of the larger organizations who are primarily accountants to assume the functions of the industrial engineer and to attempt work in both fields. This should not be so, for the qualifications, experience and training which insure success in one field are not those which necessarily produce satisfactory results in the other field. This may be judged from a comparision of the functions of cost accountant and the industrial engineer. The former deals with costs as he finds them, taking his data from the operations regardless of the degree of efficiency or inefficiency with which they may be preformed, and upon such information he bases his records and conclusions. Undoubtedly this gives an accurate outline of costs as they exist and if such information is properly analysed it may point the way to some of the most glaring faults in the plants or methods. To carry it even further by comparing different costs covering the same work or the same operation in the same plant the fluctuations in costs may be detected. It will be seen, then, that cost accounting can give accurate costs and that the fluctuations in cost may be determined but is does not provide any standard basis upon which to compare or judge the efficiency with which each operation is performed or the relative efficiency of the plant as a unit and as a result does not provide a foundation upon which costs may be intelligently reduced.

What the Industrial Engineer Deals With

On the other hand, the industrial engineer does not deal with costs as they are, but as they should be. Experience and training have developed a foundation upon which the relative efficiency of man, machines and operations may be judged. If he is a specialist in one particular field—and it is in the best interest of all concerned that specialization should be encouraged—his work in that field should have and will have provided sufficient data upon which to determine deflnite standards of performance for men, machines and methods under varying conditions and for many different products and therefore place him in a position to accurately and intelligently judge the relative efficiency of each minute operation as well as of more important operations, whole departments and the plant itself. His work then will consist largely of reducing waste, both of material and labor; analyzing operations; studying methods and equipment; planning the work so that machines are operated at something approaching capacity; eliminating trouble of various kinds and in other ways striving to bring down costs to as near the standard or minimum as conditions will permit and thus provide a basis for establishing standard labor costs. When this has been accomplished the accountant still takes the costs as they exist—only by this time they are standard—and upon them builds his structure of cost data.

Have I made the difference clear? One concerns himself with recording and tabulating costs as they exist but is not concerned as to whether they are high or low, his goal being accuracy. The industrial engineer, on the other hand, is not very much concerned about recording; his attention centres rather on lowering costs in every way possible. The success of his efforts will be judged on the results as recorded by the accountant and it is clearly, therefore, in his in-

*Statistician, Forest Products Engineering Co., Chicago.

terest not to over systematize and increase the overhead by the use of a multitude of forms and red tape and the one who knows his work does not do so. If then the industrial engineer provides the ideal basis for the cost accountant that is as near minimum as conditions will permit, it is not unreasonable to suggest that the work of the industrial engineer comes before that of the cost department and that both are equally essential to the intelligent and efficient operation of a woodworking plant.

Watch Your Credit, Make Your Terms Short

And Do Not Give Anything More Away in Discounts than your Particular Locality Expects of You —Advice for the Small Mill Man—Production, Selling and Credit Tied Up Together

By O. W. Brightman*

Mr. J. A. Loetscher (in the June issue of the "Canadian Woodworker") discussed the wholesale side of the credit and discount question very thoroughly. In this discussion of his paper I shall attempt to open up the credit problems of the small mill man as effectually as I can.

It seems to me there are at least two things coming into this question that are so closely interlated that it is almost impossible to consider one without giving the other two consideration. This makes a three point consideration, production, selling and credit, and the manager who is able in a small mill to fill the three places is somewhat of a wonder to me. One man may be especially strong in the production end and still his business will be a failure without his being a salesman as well as a credit man. The selling end of any proposition requires a well trained mind, a man thoroughly versed in his product and a student of human nature but his work will come to naught if he is not able to have production behind his efforts and the credit established before hand.

The first question that must be considered when a customer comes to you for material is the one of "Can he pay for it?" I remarked to a salesman a few days ago that there were three good reasons why I did not place an order with him for lumber and stated that the first was that I did not have any money. He evidently had credits in his mind and came back quick to never mind the other reasons. The manager who must do his own selling, look after his own products and then be his own credit man must be exceedingly careful when he comes to the third role, that of determining the credit. On the other hand he must work so thoroughly and so carefully with the other sides of his character that the three will co-ordinate in making a smooth transaction that will be profitable to him and a pleasure to the customer.

Credit Problems in the Rural Districts

Those who are still dealing to some extent with the farmer have still another problem, especially this year, when the farm products are most thoroughly deflated and everything that the farmer has to buy is still more or less inflated by labor conditions. It is our experience that it is necessary to grant the farmer extra time for payment and we find him almost invariably willing to give us a note at the time his account comes due and by using this note in our bank it is possible to grant this extension of time. Our locality probably is more favorably in this respect than any other, especially where the farmer depends altogether on stock feeding and grain raising.

Those of us who are doing business in these localities are confronted with an entirely different problem of credits. It is my personal opinion that the man who does not make full use of the lien laws in granting credits is playing an extremely hazardous game at this time. It is bad enough to take the ordinary and unavoidable loss due to business mortality but I maintain that it is not necessary to take a loss where it is possible to protect yourself by a lien. It is, however, very unwise to sell an account where you know that it is going to be necessary to avail yourself of your lien rights but oftentimes it is necessary to meet unfavorable things in this way.

The frozen credit question is a serious one this year and it makes many of us curtail our business to meet this present day emergency. We can feel relieved, however, if we have enough surplus accumulated to be able to carry us through this period.

Terms and Discounts Applying to Small Man

On the question of terms, I have but little to say. Since engaging in the retail lumber and planing mill business I find that each locality settles the question of its own terms of payment and discounts. In a general way, we adhere strictly to a 60-day term on our accounts although as in the case of the farmer it is not always possible to do this, but we do try very hard to get accounts over sixty days due closed by note of as short a term as possible. By collecting these through the bank there are very few notes that are not paid at maturity.

On the question of discounts the small mill man confronts a peculiar situation in many localities. Throughout the Fox River Valley from Oshkosh to Green Bay the general contractors have asked and received from the material realer a 5% discount from all bills for the previous month provided they are paid on or before the 10th. of the month. I personally do not like this idea and in order to avoid class distinction we allow 5% to all our customers. We insist on all bills other than to the general contractor to be paid in 10 days from the date invoiced in order to secure the 5%. This has some advantages over the old 2% discount which we believe is quite universally used, inasmuch as it brings us money more promptly that we would otherwise get.

We have gone completely away from the old system of discount when a customer building a new home was allowed to finish his whole house and then come in and get the regular cash discount. The Green Bay Planing Mill Co. renders bills to its customers just as the material is delivered, whether it is to a contractor or owner.

It is my firm conviction that there never was a time when we should be as careful in making accounts or use more strenuous means to secure our accounts after they are once made than now.

We must have production undoubtedly to be able

*President, Green Bay Planing Mills, Green Bay, Wis., before the Millwork Cost Bureau.

to make the price. We must have the selling efforts necessary to produce the orders for production but above all scan your credits and make as few bad debts as you can and even at that you will find when you come to balance your books that you have some considerable amount to charge off.

We are all looking with longing eyes towards the time of so called normalcy. If I could have somebody define this word to me, I might discuss the matter with greater intelligence. I wonder who wants to go back to pre-war conditions as being normal, I for one would not be willing to make the attempt, and if today is normal then I am equally disappointed. These questions are so complicated that I only just want to bring them up before you and let each individual define for himself his own personal idea of what is normal condition. I don't care a whoop about what was the normal condition of 1912 and 1913. What we want is a 1922 stabilized situation that will give us confidence to proceed in an orderly manner.

Some people have suggested that we have precedents to follow which would indicate what is to come and that the world moves in cycles and they trace all sorts of imaginary lines across a sheet of paper to prove it but I have never been able to satisfy my mind that they know more about it than the rest of the world. They can tell us afterwards the signs that lead up to it and what you should have done. What we want righht now is someone to tell us how to do it but in the mean time watch your credit, make your terms as short as possible and don't give anything more away in discounts than your special locality expects you to.

Greater Attention to Drying Losses

Is Too Much Importance Attached to the Moisture Reducing Feature of Dry Kiln Operation at the Expense of Other Factors ?—Adequate Uniform Circulation is Probably the Most Important Element in Kiln Handling

A manufacturer of dry kilns recently made a suggestion to the effect that too much attention is being and has been given to the moisture content of kiln-dried lumber and not enough attention to the condition of the stock during the drying period and as a result the output of the kiln in many plants is not in as good condition as it should be. Whether or not there is any real foundation for this idea, it might be well to enlarge on this thought and attempt to define the goal at which both dry kiln owner and operator should aim, if they are sincere in their desire to secure the best possible results from their kiln equipment.

Undoubtedly, it is important that the stock be brought down to the desired degree of moisture content, for after all this is the sole aim of the drying and seasoning operation but in the effort to dry the lumber there are other important factors which must be given due consideration. Perhaps what prompted this suggestion was the fact that ever so often a kiln charge of lumber is ruined in an effort to dry it as quickly as possible and that the same desire for speed keeps the drying loss at a high figure, in most plants the assumption being that the attention of the operator was centered on hurrying the removal of the moisture to the exclusion of everything else.

What is Good Kiln Drying?

It might be well to start with a definition of good kilndrying. Good kiln drying might be defined as the drying of lumber by artificial means in the shortest time and with a minimum loss from spoiled lumber and degrade due to checking, warping, staining, honeycombing, etc., and so that the stock is free from strains, stresses and case-hardening. This may seem like a formidable program but if approached in a proper attitude it is not unsurmountable.

It is important that the lumber be reduced to the predetermined moisture content and it is just as important that full cognizance be taken of the other factors. Lumber that is dry but full of checks and honeycombs is worthless and regardless of whether the drying period is short or long, it is not good drying. The same may be applied, though perhaps not in the same degree, to lumber that has been case-hardened and which is full of internal strains.

Our knowledge of kiln-drying has advanced to the point where we know how, so that the solving of the drying problem resolves itself into a question of operating according to the present day theory and of obtaining equipment that will ensure the required conditions. When this is done the final result rests upon the attitude and knowledge of the kiln operator.

Of all the factors entering into the successful operation of a dry kiln, that is, exclusive of the human factor, which naturally takes first place, there is probably none quite so important as adequate, uniform circulation. If the rate of drying is too slow or if for any reason it is found advisable or disirable to shorten the drying by speeding up the drying operation, higher temperatures and lower humidities should only be considered as a last resort and then only under the most careful supervision. First, the circulation should be given attention. If it is not brisk enough or if it is sluggish and uneven in certain parts of the kiln, such faults should be corrected. It is surprising what can be accomplished in the way of improved results simply by correcting and, perhaps, increasing the circulation. This is true to such an extent that the claim is often made that with what might be called adequate, uniform circulation the output of a kiln can sometimes be doubled.

In conclusion, the rate at which the lumber is dried is all important but speed without quality is not very much good. Little, if anything, is gained, if by increasing the rate of drying the drying losses climb in proportion. The aim should be speed, but speed accompanied by minimum losses and having regard to the quality of the stock after it is dry. Perhaps there is not enough attention given to case-hardening. The tests for this trouble are simple and have been published in the "Canadian Woodworker and Furniture Manufacturer" on several occasions. If these are made at frequent intervals and resort made to steaming upon the slightest indication of case-hardening and in addition at the end of the run, it is not likely that there will be much trouble from case-hardening or internal strains of any kind.

There is not the slighest need to do a great deal of hard sand-papering on any class of work, as machines are now made to sand any shaped article.

Should Flooring Grades be Changed?

A Comparison of American and Canadian Grading Rules -- Canadian Manufacturers of Flooring Have Difficult Problem to Solve in Meeting U.S. Competition and at the Same time Maintaining a Quality Product

Manufacturers of hardwood flooring in Canada have a number of problems peculiar to their industry with which to contend. Chief among these are outside competition, high freight rates on raw material, variation in grades and uncertainty on the part of architects and contractors as to what the various grade terms represent. On top of this the question of Canadian competition is always an important factor.

It might be of interest to consider these various factors and see how they bear on the manufacturer in the marketing of hardwood flooring. Probably of first importance is the question of grades. The larger flooring producers in Canada have adopted standard grading rules which are more or less uniform. In applying these rules there is bound to be a slight difference in interpretation, depending to a certain extent on the standard of quality which has been established. Without departing very far from any set of grading rules, it is possible to grade close or grade wide or generously and produce two grades which, while coming under the same heading or trade term, vary considerably as to value. This undoubtedly occurs in the Canadian industry, and as will be pointed out later on, the price in this country is controlled by American competition. There may be a slight tendency for Canadian flooring manufacturers to stress the quality feature and to a certain extent compete on a quality instead of a price basis. It has been suggested that Canadian flooring men compete entirely on the quality of their product, each striving to outdo the other in the grading of his product. It takes considerable time to establish a grade or a reputation for flooring of a certain standard, and when the graders have been once trained to conform to this standard, it will be confusing, to say the least, if the standard were changed from time to time to meet competition.

A comparison of Canadian and American grading rules, as shown elsewhere in this article, affords an intensely interesting study. Through a difference in the definitions of the standard grades, chiefly with regard to minimum length and proportion of short material, and by establishing several extra grades, the American manufacturers are enabled to realize on the average slightly more for the run of their plants. Another feature that permits the American flooring producer to sell closer or to make larger profits, as the case may be, is the grade of the raw material which he uses.

Canadian Firms Use Higher Grade of Raw Material

There are two factors which influence the buying of raw lumber for flooring. One is the demand for the various grades of flooring. If none but the better qualities selected are being sought, it will be found necessary to purchase a higher grade of raw material so that a larger proportion of high-grade stock will result. If the call is for the medium grades, a lower quality of raw material will be found to be the most satisfactory. The other factor which determines the suitability of the raw material is the percentage of waste produced. It does not pay to handle any grade of material which gives a high percentage of waste, for the freight on the waste would practically offset any profit which might otherwise result.

In actual practice this means that the American hardwood flooring plants, particularly those situated at or near lumber—producing centres, manufacture their flooring from the lower grades of lumber, whereas the Canadian manufacturers must use better stock as they cannot afford to pay freight on any quantity of waste material. The result is that Canadian flooring manufacturers buy largely No. 1 common and better and sometimes a certain amount of F.A.S., while American flooring makers cut up No. 2 and 3 common with, perhaps, a small percentage of No. 1 common stock.

In a preceding paragraph it was intimated that the grade of material used had its effect on the quality of the grades produced. This applies particularly to lengths. It stands to reason that using the better grade lumber cannot help but mean a higher proportion of long stock which is a very desirable feature as far as the flooring buyer is concerned.

Prices Influenced by American Competition

The prices of Canadian flooring are practically governed by the American market. This holds true of thin flooring in particular. Ostensibly the Canadian producer is protected by a duty of 25%, but the difference in the freight on the finished product with all waste eliminated and the freight on the raw material in the rough is sufficient to wipe out this protection and enable American flooring men to compete in Canada on a basis of equality. While such phrases as "Buy Made-in-Canada Products" and "Patronize Home Industry" sound nice, they do not carry any weight, for a difference of $1.00 a M is often sufficient to swing the business in favor of outside concerns. This means that Canadian flooring manufacturers must watch the American market and govern themselves accordingly, and at the same time maintain the quality of their product. Canadian flooring users have been educated to high-grade material, and as a rule are not satisfied with any stock that does not come up to the mark.

Commenting on the question of grades, one large Ontario flooring manufacturer expressed himself as follows:—

"If the customer considered the quality and beauty of the floor after it was laid, he could readily be persuaded to use Canadian stock and would get better value for his money. It is a question if it would be wise for Canadian flooring manufacturers to alter their grades so as to compare with the American standard, but I am inclined to think that it would be a mistake to do so as it is generally conceded among flooring manufacturers that in meeting American competition, it is better business to have our grades higher than

Comparison of Canadian and American Rules

The Canadian rules have been adopted by the Canadian Flooring Manufacturers while the American rules are those accepted by the Oak Flooring and Maple Flooring Manufacturers' Assn.

Canadian Grading Rules

Quartered Oak

"Clear" shall have one face practically free of defects, excepting ⅜ of an inch of bright sap. The question of color shall not be considered. Lengths in this grade to be 2 to 16 feet, not over 15 per cent. under 3½ feet.

"No. 1 Grade" shall admit of small, sound knots and sap. Makes a good floor when care is taken in laying and finishing. Lengths, 1½ feet to 16 feet, and not more than 25 per cent. under 3½ feet.

Plain Oak

"Clear" shall have one face practically free of defects, excepting ⅜ of an inch of bright sap. The question of color shall not be considered. Lengths in this grade to be 2 to 16 feet, not over 15 per cent. under 3½ feet.

"No. 1 Grade" shall admit of small, sound knots and sap. Makes a good floor when care is taken in laying and finishing. Lengths, 1½ feet to 16 feet, and not more than 25 per cent. under 3½ feet.

Maple, Beech and Birch

"Selected Red or White" shall have one face clear of all defects, and selected for uniform color. Length 2 to 16 feet, not over 15 per cent. under 3½ feet.

"Clear" shall have one face practically clear, but color no defect. Green or dark streaks not over ¼ inch wide and 3 inches long, or its equivalent, and small defects which can be readily removed by the ordinary method of scraping after the Flooring has been laid, permitted. Tongue will permit of one-half short for 25 per cent. of length. This grade must have one face free from all shake and checks. Lengths 2 to 16 ft. but not over 15 per cent. under 3½ feet.

"No. 1 Grade" shall have largely one clear face, admitting occasional small, sound knots, and other slight imperfections. Also small checks not over 2½ inches long, providing they run parallel with edge, allowed. Color no defect. Lengths, 1½ feet to 16 feet, not over 30 per cent. under 3½ feet.

"Factory Grade" shall admit of knots and other imperfections. Will make a serviceable floor with some cutting. Lengths, 1 foot and up, not more than 50 per cent. under 3½ feet.

American Grading Rules

Quartered Oak

"Clear" shall have one face practically free of defects, except ⅜ of an inch of bright sap; the question of color shall not be considered; lengths in this grade to be 2 feet and up, not to exceed 15 per cent. under 4 feet.

"Sap Clear" shall have one face practically free of defects, but will admit unlimited bright sap. The question of color shall not be considered. Lengths in this grade to be 1 foot and up.

"Select" may contain bright sap, and will admit pin-worm holes, slight imperfections in dressing, or a small tight knot, not to exceed 1 to every 3 feet in length; lengths to be 1 foot and up.

Plain Oak

"Clear" shall have one face practically free of defects, except ⅜ of an inch of bright sap; the question of color shall not be considered; lengths in this grade to be 2 feet and up, not to exceed 15 per cent. under 4 feet.

"Select" may contain bright sap, and will admit pin-worm holes, slight imperfections in dressing or a small tight knot, not to exceed 1 to every 3 feet in length; lengths to be 1 foot and up.

"No. 1 Common" shall be of such nature as will make and lay a sound floor without cutting. Lenghts 1 foot and up.

Birch, Beech and Maple

"White Clear" is special stock manufactured from white clear maple lumber from the outside of the log, winter-sawed and end-piled in sheds to prevent staining, is almost ivory white, and is the finest grade of maple flooring it is possible to produce.

"Red Clear" beech and "Red Clear" birch are manufactured from all-red face stock, especially selected for color and are free from all defects. The color is a rich warm tint peculiar to no other wood.

"Clear"—13/16-inch and thicker, shall have one face practically free of all defects, but the question of color shall not be considered. Standard lengths in all widths in this grade shall be trimmed 2 to 16 feet; the proposition of lengths 2 to 3½ feet inclusive shall be what the stock will produce up to 20 per cent.

"No. 1"—13/16-inch and thicker, will admit of tight, sound knots and slight imperfections in dressing, but must lay without waste. Standard lengths in all widths in this grade shall be trimmed 1½ to 16 feet; the proposition of lengths 1½ to 3½ feet inclusive shall be what the stock will produce up to 40 per cent.

"Factory"—13/16-inch and thicker, must be of such character as will lay and give a good serviceable floor, with some cutting. Standard lengths in all widths in this grade shall be trimmed 1 to 16 feet; the proportion of lengths 1 to 3½ feet inclusive shall be what the stock will produce up to 60 per cent.

theirs and to educate the purchasing public in this respect so that they will demand our grades rather than American stock. I do not think it would be advisable to make any change in Canadian standards as the grades now prevailing provide stock that makes the best possible use of the lumber that is available for the manufacturer of hardwood flooring."

Terms Not Understood

A considerable amount of confusion exists among architects, contractors and flooring users as to the definition and quality of the various grades. These men do not seem to be conversant with the different grades put up, and as a result often specify one grade when they really mean another. Thus specifications for a job often call for "selected clears," "No. 1 clear," "No. 1 selects" or even "No. 1 flooring," and, no doubt, in each case the best grade is expected. This misunderstanding could readily be cleared up through a little educational publicity work in the proper significance of grading definitions.

The air suction in a chip and dust removing installation is determined by the fan and the number of openings connected to the inlet side.

When the finishing process of any class of work is very excessive, it means that the sawing and the planing has been done very badly, and the sanding machines are not being worked to their fullest capacity.

Band Resaws Will Prove Money Savers

Essential Machines in the Furniture Factory as They Reduce the Raw Material Inexpensively and Efficiently to Correct Workable Sizes With the Minimum Loss in Stock.

By Eugene T. Thompson*

The small band resaw is one of the most essential machines in a furniture or woodworking factory. No other conclusion is possible after an investigation into the use of the band resaw in connection with the manufacture of furniture.

The first reason for the band resaw is, of course, its ability to re-manufacture rough stock into any dimensions required. The average thickness of lumber purchased by furniture manufacturers is 1", 1½" and 2". In order to make up stock of 3/8" or thereabouts, as is required in practically all lines, without a resaw would mean sizing an inch board down to 3/8" which would of course be a criminal waste of good material and labor. With the resaw, however, one inch stock can be split, making two 3/8" pieces when finally dressed. If 1½" stock is used, three 3/8" can be made by means of the resaw.

It is admittedly impossible for the manufacturer to buy lumber in thickness that will dress down without waste, to the sizes he uses. The resaw, therefore, offers the cheapest and most efficient method for arriving at the desired results as practically no lumber is wasted. Another consideration is that a manufacturer can buy lumber of varying thickness at a price below the market for standard dimensions and then resaw this into sizes to suit his particular requirements.

Resaw Saves Other Operations

The resaw, however, has a use beyond that of cutting the raw material into workable dimensions as the following will indicate: In one factory, drawer sides which average 3/8" thick are made up of 1" stock. They are sent through the molder, which cuts a groove on both sides, rounds the outer edge and dresses both sides. Then it is sent to the resaw and split in the centre and the two pieces after being dressed on the reverse side are completed.

The advantage of this method is at once evident. Until the stock is finally resawed, two pieces are put through the molder and other operations at the cost of one. Instead of the resawing operation being first, it comes at the end of the manufacturing process. This same method is adaptable in many ways, effecting substantial savings in labor costs.

In the majority of plants, the rough lumber is first cut off according to lengths and to remove knots and other bad spots, then ripped so as to get only good clear lumber. It is then glued into blocks averaging 24" x 36" and from the glue rooms, really starts on its progress towards finished material.

Where Money is Saved

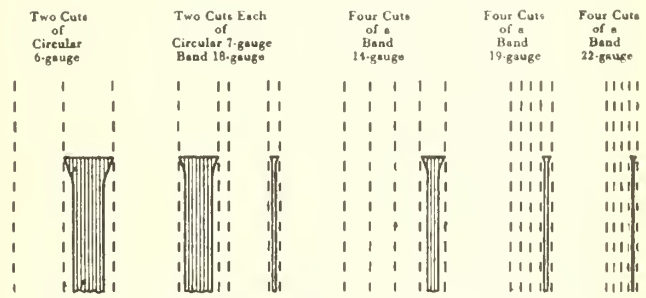
The resaw is called upon to handle a good deal of this stock from the glue room, as it will automatically centre saw, splitting each piece exactly in the middle or it will gauge saw, making three or more pieces of the same thickness, as required. Thus the rough material is reduced to a condition, where only the minimum amount of stock is removed in the surfacing operation and it is here where the money is saved and the resaw comes into its own.

In talking with a superintendent of a large factory, with a record of twenty-eight years behind him, the remark was made: "Could you get along without your resaw?"

"Get along without it?" he repeated the question. "I should say not! There isn't a more essential machine in my factory. If there is such a strange animal as a furniture factory without a resaw, I'll show you an outfit losing money faster in their production than the stockholders can shovel it in through the front door."

The above sums up the resaw situation in the furniture factory. It is an absolutely essential machine as it reduces the raw material inexpensively and efficiently to the correct workable sizes with a minimum loss in stock. Without a medium of this kind, the waste in raw material would be tremendous.

This applies, of course, to the band resaws. The circular resaw, a few of which are still in use, will cut up stock to the desired thickness but the loss in the saw kerf of a circular saw compared to that of a band saw, is so great that the circular saw's operating cost is much higher. Furthermore, the circular resaw requires considerably more power than the band resaw.



Two Cuts of Circular 6-gauge
Two Cuts Each of Circular 7-gauge Band 18-gauge
Four Cuts of a Band 14-gauge
Four Cuts of a Band 19-gauge
Four Cuts of a Band 22-gauge

A comparison of the cuts of various types of saws, indicating the advantage of band sawing over circular sawing

Band Resaws Remove less Kerf than Circular Resaws

The band resaw removes about 66% less kerf than the circular resaw, which would otherwise be a direct loss and one that will show up in gigantic proportions on the operation sheets at the end of the year. The difference in saw kerf is illustrated by the attached diagram.

It is seldom in a furniture factory that you find a resaw with wheels larger than 54 in. equipped to carry a six or seven inch saw, 18 to 22 gauge in thickness and about 26 feet in length. Such a machine with a roll opening of 14 or 16 in. and a depth of cut of 30 in. will handle any stock required in furniture work.

The majority of factory resaws have wheels from 44 to 48" in diameter, carrying 18 to 22 gauge saws, about 23 feet in length. The standard machine of these sizes usually has a roll opening of 12 1/2" with

*Of the McDonough Manufacturing Co., Eau Claire, Wis.

6 1/4" on each side of the saw, with a depth of cut of 24 or 25", which is ample capacity. Resaws of these sizes require from 20 to 40 horse power, depending, of course, on the kind of stock, its width, thickness and the rate of feed.

Resaws are inexpensive machines to operate and keep up. Frequently, these machines run for ten years without the necessity of replacing even a gear. They are easy to keep in alignment and with proper attention to oiling and to being kept free from sawdust will equal in length of service any machine in a woodworking plant.

Importance of Properly Conditioned Saws

Outside of proper oiling, cleanliness and alignment for wear of the machine itself, the most important consideration in the successful operation of a band resaw, is the condition of the saws. Many manufacturers of furniture try to economize in their rooms by not installing the necessary equipment to properly sharpen, wedge and tension the 4, 5" or 6" wide saw blades for the resaw. This is false economy as saws not properly put up will not operate efficiently and frequently spoil good lumber in miscuts, by running off, sawing thick and thin or leading out of the cut at the centre, which is entirely caused by poorly conditioned saws.

If your resaw is not doing good work, but appears to be mechanically correct, look into the condition of your saws, and satisfy yourself that the man who is doing your filing knows how to handle a wide band saw and has the equipment to do the work properly.

The finest resaw and the best saw in the world will make a sorry showing if the filer is not conversant with his duties.

The writer recently had an experience that will illustrate. A certain well-known make of resaw was not performing as it should and some rather harsh things were said about the machine. An investigation showed that the man who had charge of the saws, which were over 25 feet in length, had never done that class of work. When a saw got dull, he filed the teeth by hand, and put it back on the machine without a thought as to the tension or the set of the teeth. It was only natural that the saw did not run true and that they had trouble in making anything that even looked like good stock. A competent saw filer with some filing room equipment soon overcame all difficulty.

The majority of resaw troubles in a plant where only the wide and long band saws are used on such a machine can be laid to the improper handling of the saw. As the resaw is such an essential machine and can do so much towards reducing production costs in the saving of material, it is certainly deserving of the necessary equipment and help to keep it in first-class operating condition.

If you stone the saw down do it lightly, and be careful only to take off the metal above the stone marks .

A dirty glue pot will often spoil a fresh lot of glue. Cleanliness with glue means greater strength and fewer broken joints..

A small pipe connected with a fan is a big help to a fret cutting machine, as it directs the air which removes the dust from the lines on the wood.

Douglas Fir for Washer Tubs

The Pathologist of the Forest Products Laboratories of Canada Comments on an Article on the Above Topic Which Appeared in the June Issue

In connection with the article in the June issue of the "Canadian Woodworker," entitled "Douglas Fir for Washer Tubs," the following letter has been received from R. J. Blair, pathologist of the Forest Product Laboratories of Canada:

Montreal, July 3rd 1922

Editor, Canadian Woodworker:

My attention has been drawn to an article on "Douglas Fir for Washer Tubs" by W. McD. Tait, which appears on page 64 of the "Canadian Woodworker" for June 1922 where I am somewhat surprised to find myself quoted as an authority on the subject of washer tubs.

The following explanation will make clear my reasons for writing you in this connection. In May 1921 a letter was received at the Forest Products Laboratories of Canada from Mr. Tait asking for information as to the suitability of Douglas Fir for washer tubs, and in reply there was mailed to him a report on the subject [which appears below] If you will compare this report with Mr. Tait's article you will find that the two statements are hardly in accord with each other. I have never had the privilege of seeing one of Mr. Tait's washer tubs and you will find the statement in the report to him "Without examining one of the machines it is impossible to make a definite statement regarding the suitability of fir for its construction." When this sentence is omitted (as it is in Mr. Tait's article) the meaning is very materially changed. This report was not prepared for publication and if Mr. Tait chose to use it for an article he should have been more careful to use it in a way that would not create a wrong impression.

The article is also in error in stating that tests were carried out at the Forest Product Laboratories in Montreal. No such tests were made and the laboratories made no offer to perform such tests.

Forest Product Laboratories of Canada
Yours truly,
R. J. Blair
Pathologist

The report to which Mr. Blair refers and which was submitted by him to Mr. Tait is reprinted as follows:

Douglas Fir for Washer Tubs

When wood is used for such purposes as the manufacture of laundry tubs there are two independent relations regarding moisture which may be considered. These two conditions are the shrinkage and swelling of the wood due to its moisture content and decay of the wood which results from keeping it permanently moist.

Without examining one of the machines, it is impossible to make a definite statement regarding the suitability of fir for its construction. The special advantage over Douglas fir which Louisiana cypress is supposed to possess is its greater resistance to agencies causing decay. It is not thought, however, that this consideration should be of any importance in

laundry tubs. With a washing machine used once a week and stored in a dry place the tendency of the wood to decay would be so slight that Douglas fir should be suitable. If the wooden part of the machine is encased in a tight metal casing so that the wood might remain permanently moist the cypress would be preferrable.

Shrinkage or swelling of the wood is the other feature calling for attention. Such changes in the size of the pieces are due to the contraction or expansion of the cell walls of the wood structure which changes occur as a result of change in the moisture content of the wood. The shrinkage of a piece of lumber tangentially to the annual rings is about twice as great as it is in a radial direction, that is, a line running through the centre of the tree. Lengthwise in the piece of lumber the shrinkage is very slight.

Water exists in wood either as free water content in the cell cavities or as water absorbed in the cell walls. When wood contains just enough moisture to saturate the cell walls it is said to be at the fibre saturation point. Any water in excess of this which the wood may contain is in the form of free water in the cell cavities. Removal of the free water has no apparent effect upon the properties of the wood except to reduce its weight but as soon as any of the absorbed water is removed the wood begins to shrink. Since the free water is the first to be removed shrinkage does not begin, as a rule, until fibre saturation point is reached. For most woods the fibre saturation point corresponds to a moisture content of 25 to 30 per cent of the dry weight of the wood. If wood below the fibre saturation point is allowed to absorb moisture it will swell. This swelling for most woods reaches its maximum at the fibre saturation point and further absorption of moisture has no effect on the size.

It would not appear that the differences in shrinkage of Douglas fir as compared with that of cypress should be of sufficient extent to make the fir unsuitable for the manufacture of tubs. The shrinkage of the two woods when compared in different ways is as follows:—

	Per cent Shrinkage		
Kind of wood	In volume	In radial direction passing through centre of tree	In tangential direction at right angles to the radial
Cypress	11.5	3.8	6.0
Douglas fir	11.6	4.5	7.0

Shall All Lumber be Grade-Marked?

Definition of New Lumber Grading Standardization Program—Requirements of Wood-Users the Basis for New Grades—All Lumber to be Branded and Grade-Marked?

By J. F. Hirt*

Standardizing nomenclature is the engineering term for establishing a common language or common term of expression. When an industry lacks this first fundamental principle, it is obvious that very little if any progress can be made, and this is the very condition existing in the wood-using industries.

The automotive industry, although one of the latest to spring into prominence, is already far ahead of those in the woodworking field, and the remarkable achievement of the motor car manufacturers can without question be credited, in no small measure, to the able pioneer engineers and their successors, with whom they surround themselves.

The wood-using industries have been waiting patiently, often dispairingly, for the day when the manufacturers of the raw material they use would recognize the necessity for the standardization of grades and sizes or multiples thereof, which they could understand and which would more closely conform to their requirements. But they have been told that "it can't be done", the Lord Almighty grows the trees with all the variables which must be passed on to them. No one will question that variables exist and we all agree that they are great, but we are not quite so willing to agree that they cannot be reduced to conform to properly defined standards.

There are variables, and even variables of variables, in the raw materials used in practically all our industries. The leather using industries do not buy their raw material on a few vague and indefinite grade names, without any identification marks. The variables here are reduced to the most practical and economical point by the manufacturer, who produces first and foremost to the particular requirements of the various industries using his product.

The greater the number of industries using one basic raw material the more complex are the variables that enter into the manufacture of that raw material, and although lumber is one of the most outstanding examples, practically nothing has been done in the direction of standardization.

Present Definitions Vague

For all they mean, the present vague grade definitions could just as well be expressed as, excellent, good, fair, medium and poor. A. No. 1 common board may be required to cut 66-2/3% clear but this means nothing because we do not know the use to which it will be put. It will cut clear according to the sizes and quality requirements of one or more industries.

In the past, wood-using manufacturers have been much safer in carefully selecting their lumber manufacturer or dealer than in considering grades, simply because grades varied more according to the honesty and integrity of the latter than to any other factor. This is a deplorable situation and has continued to exist only because of the lack of concerted action either by a group of wood-using manufacturers or by the lumber manufacturers themselves. Perhaps if the people of this country had known that every time they bought a piece of furniture containing, say,

*Vice-president, Forest Products Engineering Co., Manhattan Building, Chicago.

twenty-five feet of lumber, they have actually been paying for more than seventy five feet, this condition would not exist today. Not only this but the cost of the skilled labor used in working up this waste is even more staggering.

When the U. S. Secretary of Commerce, Hon. Herbert C. Hoover, suggested to lumber manufacturers that their efforts be directed toward standardizing sizes and nomenclature, determination of a system of grade branding and other means for affording protection of the public, he may not only have known more about these conditions than the dissenting minority would lead the public to believe, but he has actually prepared and laid a foundation for the emancipation of the lumber industry, which will soon be productive of noteworthy economies to all concerned. The problems should, however, not be considered a mere routine chore; it will take years to establish an efficient grading system and in addition, the requirements, just as in other industries, will change from time to time as old stabilized products are eliminated from manufacture and as new ones are added. The establishment of clearly defined grading rules will only be brought about by giving equal consideration to the available supply of timber and to all the finished products manufactured therefrom.

Why Dimension is Not Successful

It is evident that mill cuttings will need to be as near clear as usable as it will be found practical to make them. On the other hand, there is at least one objection to the manufacture of dimension stock. Dimension stock is not yet successful because there is no simple, practical method of kiln drying it. Every board produced will usually develop some end checking as the inherent moisture leaves it and the resultant shrinkage takes place. Consequently, the longer the board the less waste in per cent of the whole will result from end checking. This problem, therefore, must be taken into careful consideration until such time as it may be found more economical to dry lumber scientifically, green from the tree.

There are only a few large manufacturers who can at present hope to profitably manufacture dimension stock according to recently established practices and these few must undertake and succeed in proving to wood users the merits of this stock through more disinterested channels than their own organizations. If we want to consider dimension stock as making not only one unit piece but any number of multiple units, then the term will fit our new grading systems to a considerable extent, but it would again be a general term leading to more confusion and therefore, should be avoided in the interest of standardizing nomenclature or grade terms.

How to Establish a Grading System

In order to establish a grading system that will be of real tangible value, it will first be necessary to prejare the following data.

1. Make a complete engineering product analysis of all articles made of wood in all industries. This will consist of: (a) Dissecting each article into unit parts; (b) classification of all parts according to the kind of wood and dimensions; (c) Tabulation of manufacturing operations performed on each part and in the sequence they are performed. The purpose of this engineering analysis is, first to determine accurately the raw material requirements of all the wood-using industries and, second, to determine the labor that will be saved by a proper grading system.

2. Standardization of sizes: (a) According to products of the various industries. This can be accomplished through enlisting the co-operation of architects, designers and construction engineers. (b) According to the available timber supply, for not until the requirements of the wood using industries are known, can they be intelligently filled.

It may be helpful to indicate how chats can be developed which will enable the lumber manufacturer to cut logs of all descriptions most economically and although each industry has its own individual practices and therefore can not be used as a concrete example, an interesting illustration is found in the method by which the packing industry classifies and cuts beef. Instead of showing the cuts from the logs by name as in cutting beef, it will be necessary to indicate the various boards in the log charts by grade name, each one giving the optional cuts to make.

Practical mill men decide their cut now according to their own individual ideas, and it is unnecessary to state that there are many different ideas. As there must be one best way, why not determine which one that is and standardize it? When a grading system has been established, lumber should certainly be marked strictly in accordance with it. There is, however, every reason for not grade marking while the present vague system of grading is in effect

No Real Objections to Grade Marking

The objections to grade marking are not consistent. The legitimate lumber dealer does not fear this practice and those who still object take a look around and see other materials are manufactured so near to the completed product as lumber, that do not bear the grade and trade mark of the manufacturer.

It would be a fine state of affairs if when we walked into a cigar store we found the shevles and show cases filled with open boxes none of which were labelled or marked. The dealer may or may not be honest and if asked for "No. 1 common" the chances are he might hand us a "No. 2 common" rather than a "Select" or a "First and Seconds." There is likely no other commodity we buy regarding which we are given so little information as in the case of lumber.

Manufacturers are always proud of their trade marks and there is this one point for dealers to consider; trade and grade marks have never put anyone out of business. The reputable dealer is quite proud and profits most when he handles a high grade line, but the Canadian people are not quite willing to take the dealer's word that the goods are high grade. They would rather judge by the grade and trade mark.

Death of Robert S. Harmer

Robert S. Harmer, one of Canada's most prominent manufacturers, died at his home in Connaught Circle, Cedarvale, in his 70th year. The late Mr. Harmer was president of the Canada Furniture Manufacturers, Woodstock, Ont., and the Seaman, Kent Company, Toronto. He was born in England and came to this country when a boy.

When it is necessary to throw a belt off a moving pulley, put the stick against the part of the belt which is travelling to the pulley, then press against it, and it will guide the belt from the pulley.

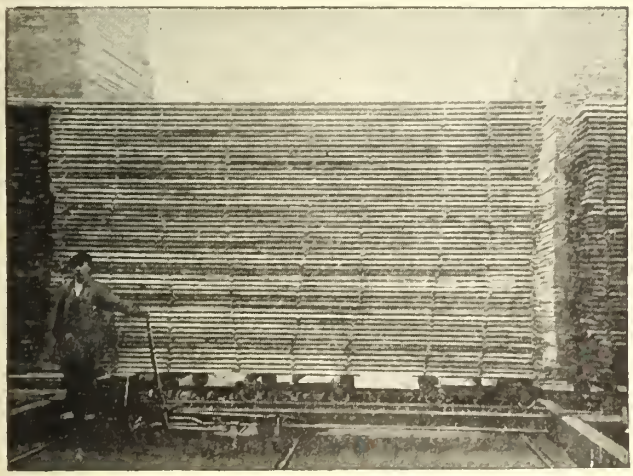
Save Five Men and Two-Thirds the Time

In Handling Lumber in the Yard and Transferring it to and from the Kiln—An Electrically Operated Transfer Car Reduces the Cost of a Heavy and Risky Operation

How do you handle lumber in the yard and transfer it from yard to kiln? Do not follow the ordinary method which is somewhat as follows:—The yard foreman has to get all his men together who are scattered in various parts of the yard—some are on top of a high pile, others in lumber cars, others stacking.

The old way—hand power

By the time he has obtained his crew of six to eight men, considerable time is lost. Then they start tugging and pushing the loaded kiln car to get it on to the transfer car. In the winter it is often necessary to first clean away the snow and ice before the men are able to move the car, and then oftentimes it is



The new way—electric power

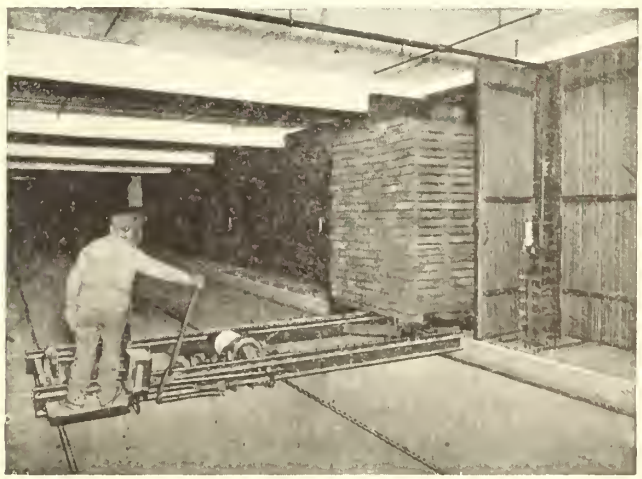
necessary to send to the mill or elsewhere for additional help. Finally the car is moved on to the transfer car and started on its way to the dry kiln—always a slow, drawn-out operation. Eventually the car is spotted in front of the kiln and again the positions of the men are changed to start the loaded kiln car into the kiln. This is frequently a dangerous job on account of the fact that the kilns have no floors. In many cases it takes as long as four hours to change a single kiln and about the same time to unload one.

Does the above description tally with the procedure adopted in your yard? If it does, you are no different from hundreds of other millmen who have to use a method so wasteful of time and money. It means heavy work for the men, frequent delays through stoppages or accidents, and a considerable element of danger. All these help run up that factor in your cost of operation known as "yard burden."

The illustrations show a method by which the handling and transferring of lumber in the yard can

Pulling a loaded kiln car on to a Pullman transfer car, by one man

be accomplished with one man through the medium of an electrically-operated transfer car which has been put on the market by the Pullman Coach Co., Chicago. It is stated by those who have made use of



Loading or unloading kiln by reversing motor only

this equipment, that one man can take a loaded kiln car of lumber from the yard to and from the dry kiln, to dry storage and out again, into the machine room, to any place to and from the yard in about one-third of the time now required by six to eight men. With the Pullman transfer car any size load, either cross

pile or end pile, may be pulled. When removing loaded kiln cars from the kiln, the operator simply hooks on to the loaded car and pulls it on to the transfer car. If he is loading the kiln, he runs the drum in a reverse direction and pulls or pushes the load into the kiln.

The car is electrically operated, the current being supplied by a three-finger collector system, by overhead trolley or by extension cable. The motor and all mechanical parts are protected from the weather, and while very compactly arranged, are easily accessible for adjustment.

Should the Special Millwork Plant Buy or Manufacture Its Stock Millwork?

Plants Equipped for Special Lines can Hardly Make Stock Goods at a Price Comparable with That for which They can be Purchased—Certain Considerations, However, Favor the Production of Standard Items by Special-Work Mills

By H. S. Sawyer*

In submitting a paper on the subject"Should the Special-Work Plant buy or manufacture its Stock Millwork" it seems to me there is presented a problem in which we are deeply interested and one that has caused many of us a lot of worry. If we consider the side of buying the items of sash, doors, mouldings, frames and some of the standard sizes of cabinet work, I believe a majority vote would favor this action. There is not one of these items that can not be purchased from some one at a lower price than would be our cost of manufacture. For the special-work plant to attempt to make stock doors and sash at a price in line with what they might be bought would be an impossibility. First on account of quantity production due to equipment and routine system of the stock plants and also to the difference in wage scales of the workers the special work plant would have to use. Conditions existing in different plants or localities would undoubtedly modify such conclusions on some items. One might have such a diversity of frames to make that the investment in lumber would be a considerable item. If the stock frames were made it would result in a quicker turnover and a reduction on overhead in this department.

Stock patterns of interior mouldings can be also purchased at lower prices than our manufacturing cost but uniformity of pattern combined with condition of finish in which these are delivered to the contractor will govern largely the purchase of this material. On cabinet work we find the same to be true; any standard layout can be purchased at prices that to the special plant would be suicide. We should consider, however, there are slack times in the special plant when the making of stock mouldings and certain kinds of case work could be utilized to keep together the organization and save in operation expenses.

Reputation on a Quality Product

These points as considered are all based on the immediate dollars and cents return but we know this is in some cases the short-sighted policy. The reputation of a concern of furnishing a high class product and maintaining such a standard will assure the future of the business and should be the object to be obtained. Will then the manufacture of many stock items, which will be recognized as the product of the concern, outweigh the difference in the cost of production? Here is where another point that has given me concern might be considered, the growing tendency of lumber yards to stock all of the above items that constitute most of the mill work requirements of moderate priced homes. If Mr. Millman indicates by his example that the purchase of K. D. frames, yellow pine trim, outside mouldings as well as sash and doors are satisfactory for the trade he supplies, then Mr. Lumber man is fortified with a strong argument that his stock is just as good. The lumber dealer has in many cases the first chance at the house bill and will naturally be able to sell many jobs if the owner or contractor thinks he is getting equal service. As I said before, the reputation of the mill on the class of work furnished will have a bearing on the amount of this business that can be controlled. Consideration of this must be given in deciding how far to go with the purchase of stock materials, or the special plant will face the problem of adding lumber to its stock to meet this competition.

I wonder if the difficulty in adjustment of operators' wages to present living conditions may not have some bearing on the need of purchasing as much of the stock items as possible. Certainly the workman must be made to see that unwillingness to recede from the high point of the past few years in his pay will force the special plant to make less and less of the stock items and therefore loose to these workers a part of their employment. The special-works plants we are considering are the ones located in cities where their business includes furnishing all the items of millwork that enter into the building activities of their city. This means that the volume of sales is greatly affected by the amount of stock material they sell. To me it therefore seems a case for the individual to decide what he must do, either buy all he can and take his chance on holding his share of the stock work against all competition on these items, or limit his buying and build his reputation on a higher service of product which will command a higher price.

Deep gullets does not mean fast cutting, but is always results in a weak saw.

Emery wheels and all grinders which make a good deal of abrasive dust should be lubricated by grease forced into the bearings by brass or iron cups.

Should a large saw have a riving knife? It depends, but as far as possible, every effort should be made to use one on every saw bench.

*President, Sawyer and Georgens Co., Joliet, Ill., before the Millwork Cost Bureau.

Bringing the Machine to the Job

Portable Bench Woodworking Machinery Opens the Way to Cutting Costs in the Woodworking Plant—Operations Hitherto Performed by Hand May Now be Handled by Machine

Back there in the early days, when the man who originated the idea of portable bench woodworking machinery was still operating a large pattern shop he often wondered how much time was being lost by each one of his men in walking to and from the large stationary machines, changing the set up, starting the motor and often waiting for other men to finish using the machine.

How much more convenient, he began to think, it would be to place machines at the bench where the man was working thus saving the time lost in travelling over to the machine. Another idea seemed to link itself with the first idea and should be considered in connection with the idea of moving the machine to the job—that idea related to the size of the work to be done on the machines. There is a lot of work done at the benches by hand because this work (and it is the planing and cutting of smaller stock incident to assembling and fitting in cabinet as well as pattern work) cannot be done on large machines; the work is too small for the large throat openings and consequently accurate and safe operation is not possible. Linking these two ideas together, the scheme is to do as much of the work as possible at the bench and avoid travelling to the big machines so often, using a smaller machine so that this work which was being done at the bench by hand could be done on machines.

There were no machines on the market at that time except the larger ones, consequently, this man found it necessary to design and make a number of small planers or jointers. He decided upon a planer four inches wide as one of the ideal size to supplement the larger jointer and to make it possible to do at the bench a lot of that work they were doing on large machines and also that work of planing, fitting, jointing, etc., which they were doing by hand.

Operates From Electric Light Socket

He built twelve and placed one between each two pattern makers. He equipped them with small fractional horse-power motors so that they would operate from the electric lighting circuit and not make it necessary to run a power line to each bench. The fact that these machines operated from the light circuit was found later to be a great convenience, for the machines could be taken anywhere about the shop or out on jobs and operated wherever an electric light socket was available. The time thus saved in his shop by these conveniently located machines and the fact that a lot of work was being done more accurately and quickly, by machines, soon made it possible to cut down the labor charge on the job work and resulted in his being able to turn out better work at a lower cost.

There was no thought of going into the business of manufacturing machinery in the mind of this man who originated the bench machine idea; he made the machines for his shop and that ended it, but you cannot hold back a good idea—it is bound to live. Therefore, it was not long until other manufacturers, realizing their disadvantages without equipment that prevented so many trips to the big machines and made it necessary to do so much work by hand, urged our friend to make machines for them. The result was that he did and today is in that line of business exclusively.

The demand for the planer grew rapidly but the idea spread and requests for machines for other operations began to come in and from a great variety of industries.

Today you will find these planers, small jointers, circular and band saws in thousands of pattern, cabinet and carpenter shops, furniture factories in the designing, upfitting, cabinet, assembling and shipping departments, sash and blind plants and shipping rooms; in fact wherever wood is worked you are bound to find these machines saving wasted steps and hand work. Hence carpenters take these portable machines with them wherever the job may be, plug them into the electric light socket and work. Warehousemen send the machines out on jobs and cut crates to fit the pieces they are packing, etc. In the six years that the manufacturer referred to above has been manufacturing portable bench machinery he has sold over fourteen thousand machines.

Sturtevant's Unique Catalogue

B. F. Sturtevant Co., of Hyde Parke, Boston, Mass., manufacturers of the high humidity dry kiln, have recently issued an attractive publication entitled "The Question and the Answer." The edition is remarkable by reason of the construction of the cover and fly-leaf. The cover is a real wool veneer with a paste board and paper backing. It is a product of the Japanese art. Besides being of interest to the lumber industry, the specimen is of particular concern to the veneer people.

To Make Motor Bodies

Messrs. E. Nicholson & Son, of St. Catharines, Ont., who have been in the building and contracting business for the past 40 years, have branched out into the manufacture of commercial motor bodies including hurses and omnibuses and have extended their premises which now include a blacksmith shop, paint shop and auto body building shop. Business is reported as brisk and further additions are contemplated shortly.

If you have a very large number of machines and only one-third are worked, the cost of running them is far greater than those run in a smaller mill plant.

The joiner who imagines that he can do better hand work than any machine has not seen some of the best work done by machinery.

Does the belt always run to the highest side of the pulley?

How do Common Styles of Boxes Compare?

The Advantages and Disadvantages of Seven Types of Nailed Wooden Boxes That May be Regarded as Standard, are Described in a Bulletin of the Forest Products Laboratories

There are seven forms of nailed wooden boxes so universally used that they may be called the standard styles of nailed boxes. These boxes can be adapted to a wide range of uses, and it is the experience of the Forest Products Laboratory, Madison, Wis., that in meeting the majority of packing problems they are the most efficient of the nailed boxes. The advantages and disadvantages of each style, as revealed in laboratory tests and observations of boxes in commercial service, are given below.

In style 1, the grain of the ends and sides runs approximately parallel to the top and bottom surfaces. One of the common failures in this type of box is splitting of the ends and sides, or failure of the joints in these parts, since the only resistance to such failure lies in the strength of the joints, if present, or in the strength of the wood in tension across the grain, which is not large and is extremely variable in any species of wood. The smaller holding power of nails driven into end grain as compared with side grain is another source of weakness.

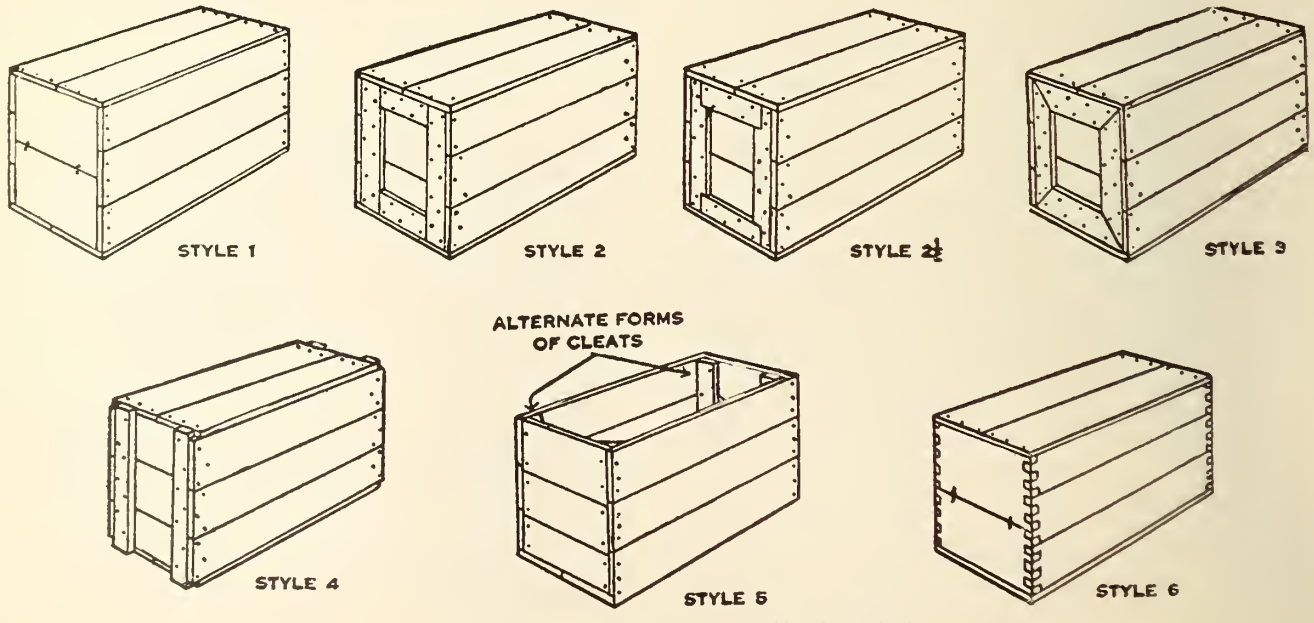
To improve on style 1 ends, and guard against the liability of complete failure from splitting of ends and sides, rectangular and sometimes triangular corner cleats nailed to the inside of the end (style 5) are added when the character of the contents permits. This construction does not increase the displacement of the box and is, therefore, not objectionable in that respect. If these cleats can be made large enough, the sides may also be nailed to them, which, of course, increases the strength of the nailing at this point. These inside cleats should be shorter than the inside depth of the box, so that if the sides and ends shrink, the cleats will not cause an opening of the joints. In all boxes with cleated ends, the nails holding the cleats to the ends should be long enough to permit a good clinch, and should be spaced approximately the same as the nails in the adjacent edges of the box.

Outside Cleats

The most common method of preventing box ends from splitting and of supplementing the holding power of nails driven into the end grain is the addition of two outside cleats on each end as shown in style 4. These cleats should be of the same thickness as the end so that the same size of nail may be used in them. The nails should be staggered in the ends and cleats; this permits a closer spacing of the nails and results in a stronger joint than is obtained by driving the nails in a single row. The holding power of the nails is supplemented most effectively by the use of denser woods in ends and cleats.

The cleats in style 4 boxes should be long enough to come nearly flush with the outer surfaces of the top and bottom. They will thus aid in keeping the top and bottom in place and will also take some of the thrust which comes on the nails in the top and bottom when the box is dropped on a corner. If the cleats are made to come exactly flush with the outer surfaces of the top and bottom, and shrinkage occurs later, it may cause the ends of the cleats to project beyond the top and bottom, and they may be pulled loose if the box is handled so that they catch on some object. The amount that the cleats should be cut short to allow for shrinkage depends on the moisture content of the lumber at the time the box is constructed and the storage conditions afterward. Usually an allowance of from 1/8 to 3/16-in. at each end will be sufficient.

The addition of the two horizontal cleats in styles



Seven styles of boxes that are considered standard

2, 2½, and 3 permits a reduction in the thickness of the end boards from the thickness of the cleats to that of the sides, top, and bottom, in which case all the nails should be driven into the cleats. Or the cleats and end boards may be the same thickness and the nails staggered in two rows. The usual failures in these styles of boxes are pulling of the nails from ends and cleats, shearing out the nails to the ends of the sides, top, and bottom, and splitting of the end boards along the inner edges of the horizontal cleats, which allows a cleat with part of the end board to pull away with the top and bottom. The resistance to failure by splitting of the end is due to the strength of the end board in tension across the grain, supplemented by the action of the vertical cleats. In nailing the vertical cleats to the ends in styles 2 and 2½, it is possible to get more nails near the top and bottom edges of the box than in the mitered cleats of style 3. This more effectively prevents the box end from splitting along the horizontal cleats.

Thrust Taken by Cleats

Style 2½ has the advantage that when the bottom and top are being nailed to the cleats, the notches or steps in the vertical cleats will take the thrust that otherwise would come on the nails holding the horizontal cleats. This thrust is sometimes very severe, especially when several nails are driven at the same time into a cleat made of dense wood.

In manufacturing boxes with square ends, style 3 has the advantage that all four cleats are the same length, hence interchangeable. When a very symmetrical end is desired rather than the strongest end, the mitered cleats are preferred.

The box shown in style 6 has sides and ends joined together by a series of tenons, called "locks," which interlock and are held together by gluing. The top and bottom are usually fastened by nailing. The lock corner, if properly glued, gives a more rigid box than nailed corners, there being no appreciable distortion before failure occurs. Tests show that many failures in lockcorner boxes occur because ends and sides split, nails pull from or split edges of too thin ends, locks open, and matched joints lack sufficient strength.

Reducing Accidents by Adequate Protection

Efficient Guarding of Woodworking Machines—Regulations Covering This Important Work—Accident Prevention Live Issue—Result in Lower Compensation Assessment

A number of safety regulations, the nucleus of a code of protection methods for woodworking machinery, were recently drawn up by the Safety and Welfare Committee of the Industrial Council for the British Building Industry. These cover in a very thorough manner the protecting and guarding of a number of machines found in nearly every woodworking plant. Safety is a live issue in all branches of industry and the following recommendations, not only show the thoroughness with which the British engineers have tackled the subject, but may contain a few practical suggestions that will be found worthy of emulation:

Definitions.—"Woodworking machine" means a circular saw, plain band saw, planing machine, vertical spindle moulding machine or chain mortising machine operating on wood; "circular saw" means a circular saw working in a bench (including a rack bench) for the purpose of ripping, deep-cutting, or cross-cutting, but does not include a swing saw or other saw which is moved towards the wood; Plain band saw" means a band saw, the cutting portion of which runs in a vertical direction; "planing machine" includes a machine for overhand planing or for thicknessing or for both operations; "within reach" means within 6½ ft. from the floor or from any other point to which any person has access while the machinery is in motion; "underground room" means a room any part of which is so situated that half or more than half the whole height thereof measured from the floor to the ceiling is below the surface of the footway of the adjoining street or of the ground adjoining or nearest to the room; "gauge" means the British Standard Wire Gauge.

Part 1.—Duties of Employers.—(1) Every woodworking machine shall be provided with an efficient stopping and starting appliance, and the control of this appliance shall be in such a position as to be readily and conveniently operated by the person in charge of the machine.

(2) Every shaft, wheel, pulley, strap, band, or other device within reach by which any part of a woodworking machine receives its motion shall be securely fenced.

(3) Sufficient clear and unobstructed space shall be maintained round every woodworking machine to enable the work to be carried on without unnecessary risk.

(4) The floor surrounding every woodworking machine shall be maintained in good and level condition, and as far as practicable free from chips and other loose material, and shall not have a slippery surface.

(5) No woodworking machine shall be worked in any place which, during daylight, does not receive sufficient natural light to enable work to be carried on without unnecessary risk.

(6) The means of artifical lighting for every woodworking machine shall be adequate, and shall be so placed or shaded as to prevent direct rays of light from impinging on the eyes of the operators.

(7) (a) No woodworking machine shall be worked in any underground room in which such a machine was not worked before the date on which these Regulations came into force. (b) From and after the date on which these Regulations came into force, no woodworking machine shall be worked in any underground room unless the room is certified by an Inspector of Factories to be suitable for the purpose as regards construction, light ventilation, and in all other respects.

(8) The temperature of any room in which a woodworking machine is being worked shall not at any time fall below 50 degrees. Provided that this Regulation shall not apply to a sawmill any side of which is open to the outside air, but the workers in such a

sawmill shall be protected as far as practicable from draughts by screens or other suitable means.

(9) No woodworking machine shall be placed in charge of a person who has not been fully trained at such a machine.

(10) Every circular saw and every planing machine which is in frequent use shall be provided with efficient exhaust arrangements so as to insure that all dust and chips are drawn away from the worker at, or as near as reasonably possible to, the point at which the dust and chips are formed.

(11) Every circular saw shall be fenced as follows: (a) The part of the saw below the bench table shall be protected by two sheet metal plates, one on each side of the saw; such plates shall not be more than six inches apart and shall extend from the axis of the saw outwards to a distance of not less than 2 inches beyond the teeth of the saw, and shall, if not beaded, be of a thickness at least equal to 14 gauge, or, if beaded, be of a thickness at least equal to 20 gauge. (b) Behind and in a direct line with the saw there shall be a riving knife, which shall have a smooth surface, shall be strong, rigid, and easily adjustable, and shall also conform to the following conditions: (i) The edge of the knife nearer the saw shall form an arc of a circle having a radius not exceeding the radius of the largest saw used on the bench, and shall be fixed at the level of the bench table at a distance of not more than ¼ inch from the teeth of the saw; (ii) for a saw of a diameter of less than 24 inches the knife shall extend upwards from the bench table to within one inch of the saw, and for a saw of a diameter of 24 inches or over shall extend upwards from the bench table to a height of at least 9 inches; and (iii) except at the edge nearer the saw, the thickness of the knife shall be at least equal to the breadth of the cut of the saw. (c) The top of the saw shall be covered by a strong and easily adjustable guard, with side flanges to protect the teeth of the saw. The guard shall be kept so adjusted that the flanges of the guard on the front side of the bench shall extend below the roots of the teeth of the saw. The guard shall extend from the top of the riving knife to a point as low as practicable at the front of the saw.

(12) A suitable push-stick, at least 18 inches in length shall be kept available for use at the bench of every circular saw which is fed by hand, to enable the work to be carried on without unnecessary risk.

(13) Every plain band saw shall be guarded as follows: (a) Both sides of the bottom pulley shall be completely encased by sheet metal or other suitable materials; (b) The front of the top pulley shall be covered with sheet metal or other suitable material; (c) All portions of the blade shall be enclosed or otherwise securely guarded, except the portion of the blade between the bench table and the top guide.

(14) No planing machine which is not mechanically fed shall be used for overhand planing unless it is fitted with a cylindrical cutter block.

(15) No planing machine which is not mechanically fed shall be used for planing overhand any piece of wood less than 15 inches in length unless a safe holder is used for such piece of wood.

(16) Every planing machine used for overhand planing shall be provided with a "bridge" guard capable of covering the full length and breadth of the cutting slot in the bench, and so constructed as to be easily adjusted both in a vertical and horizontal direction.

(17) The feed roller of every planing machine used for thicknessing, except the combined machine for overhand planing and thicknessing, shall be provided with an efficient guard.

(18) The cutter of every vertical spindle moulding machine shall, when practicable, be provided with the most efficient guard having regard to the nature of the work which is being performed.

(19) For such work as cannot be performed with an efficient guard for the cutter, the wood being moulded shall, if practicable, be held in a jig or holder of such construction as to reduce as far as possible the risk of accident to the worker.

(20) A suitable "push-stick" shall be kept available for use at the bench of every vertical spindle moulding machine.

(21) The chain of every chain mortising machine shall be provided with a guard which shall enclose the cutters as far as practicable.

(22) The guards and other appliances required by these Regulations shall be maintained in proper working order, and shall be kept in position while the machinery is in motion, except when, in case of a circular saw, the use of the guards is rendered impracticable owing to the depth of the wood being sawn. The guards shall be so adjusted as to enable the work to be carried on without unnecessary risk.

(23) Regulations 11, 13, 16 and 17 shall not apply to any woodworking machine in respect of which it can be shown that other safeguards are provided and maintained which render the machine equally safe as it would be if guarded in the manner prescribed by these Regulations.

Part II.—Duties of Persons Employed.—Every person employed on a woodworking machine shall: (i) use and maintain in proper adjustment the guards provided in accordance with these Regulations: and (ii) use the "push-sticks" and holders provided in compliance with Regulations 12, 15, 19, 20.

A Story of Two Orders

The National Dry Kiln Co., of Indianapolis, Ind., have recently sent out an interesting circular entitled "A Story of Two Orders," one the largest order for dry kilns ever placed and the other a very small one representing 60 cents. The announcement contains an illustration of sixty-six freight cars conveying National Dry Kiln equipment represented in the one order, and contrasted with this there is shown an invoice for two electric heater racks. The company state that the point they wish to emphasize in the publicity is that no order is too large for them to handle efficiently and promptly, and none so small that they do not appreciate it.

Box Business in British Columbia

Reports from British Columbia indicate that the demand for boxes and crates is heavier this year than it has been for some considerable time. Canned fish, fruit and vegetables containers for local use are taking up much of the box factories' time while a heavy export trade is also being built up, especially with Australia, New Zealand, the Straits Settlements and India.

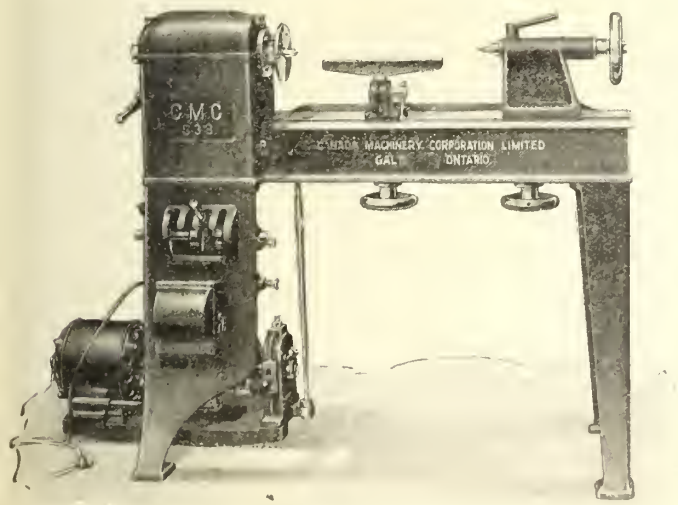
Machinery & Equipment

Manual Training Lathe

In keeping with the recent changes and improvements in the design and construction of woodworking machinery for factory use, the Canada Machinery Corporation, Ltd., Galt, Ont., have lately placed on the market their No. 838, 14" manual training lathe which will fill the requirements of educational institutions for a machine that, while meeting the peculiar needs of such institutions, also offers a machine built along the same lines as machines used in manufacturing. Not only is it suitable for manual training institutions, but it may also be installed in manufacturing plants where small and intricate turning is required.

This machine, which is illustrated herewith, is arranged for individual motor drive, the current being obtained from any electric light socket, but where more than one machine is required, they can be arranged to be driven in groups by a single motor supplying the power through an enclosed under-drive shaft.

In the design of this lathe, special attention has been paid to the rigidity of the bed and running parts. The cone in the head and the lower cone are both fitted with self-aligning ball bearings to insure ease operation. The bed and head are cast in one piece,



C.M.C. 14-inch manual training lathe

and by means of a special boring machine the head where the bearing is held is bored absolutely parallel with the bed to insure accurate alignment.

This lathe is ordinarily built with a 14" swing and a length of bed to suit individual requirements, but when so required, may be had in a larger size with a 20" swing. The spindle is of high carbon steel and arranged so that it can accommodate face plates at either end. When equipped for turning at the back end, a suitable floor stand support for rest is provided.

Ample safety for the student or operator is insured by completely inclosing the headstock and providing a wide flared left hand leg which completely covers the belt at all times.

Standard equipment furnished with the machine covers a variety of face plates, chucks, angle rests, centres and different lengths of "T" rests.

Electric Glue Pot with Rheostat Control

A glue pot with a rheostat control which permits an almost unlimited variation in temperature has been developed by the Westinghouse Electric & Manufacturing Company. The temperature of this new pot can be changed to meet different conditions, such as room temperature, climatic conditions, different grades of glue, or different kinds of work.

Some of the advantages of this device are the facts that the possibility of an unstable temperature, a frequent condition when gas is used for heating, is eliminated; a better grade of work is possible; and one cause of time waste is removed. The addition of the rheostat does not deprive the user of any of the advantages of the electric glue pot. It still remains portable since the rheostat can be laid on a bench or shelf, the cord from the rheostat to the glue pot being long enough to permit ample movement for ordinary bench work.

Westinghouse rheostat-controlled electric glue pot

The construction of the pot is rugged and simple throughout. The casing and bottom plate are made of heavy sheet steel and the glue vessel of heavy spun copper. The pot is of the dry type.

Hot Plate Veneer Re-drier

What might be termed a Canadian-made hot plate re-drier, is being manufactured by Wm. R. Perrin Co., Limited, Toronto, manufacturers, of hydraulic Veneer presses and is being distributed through the Garlock Machinery Co., Toronto. It is designed along lines very similar to the types of hot plate veneer driers, which are familiar to readers of the "Canadian Woodworker." The plates open and close in the well-known breathing movement. This permits the vapor to escape and also releases the pressure from the veneers so that the stock can shrink freely without any checking occurring. The first machine

to be manufactured is a six-plate drier with plates 54" x 84". However, the number and size of the plates can be varied to suit the needs of different plants. The necessity for having veneers and cross-banding thoroughly dry at the time of laying, is well-known to all veneer users. With equipment of this type, the moisture content of the veneers is reduced, and at the same time the pieces of veneer are straightened and dried in a flat condition. This latter point is an important one as it tends to facilitate the jointing, taping and laying operations, and also results in better joints being made. With a machine of this type the veneer user is always assured of straight, well-dried stock which means that he is in a position to produce a better veneered product and at the same time cut the cost down to a low level.

Proper Mill Arrangement and Equipment

This Millman Believes in the Single Storey Structure Constructed so that the Floor is Truck High to Facilitate Loading and Unloading—Heavy Machinery for Stock Production; Lighter Equipment for Special Work

What is the ideal design for a mill building and what equipment should it contain? This is a question the answer to which, largely depends on both the efficiency and the cost of mill production. It is well known that mills so laid out as to make impossible a continuous and direct course of material from start to finish, interfere very seriously with the volume of production and increase the cost of manufacture. Correct routing is indeed one of the essential considerations in a mill design, so that handling and rehandling might be reduced to a minimum. In this matter the location of machines has a very important bearing, but the types of machines used also affect productive capacity very considerably, the proper style of equipment to be installed depending for one thing on whether special or stock work is predominant. A very important subject is thus opened up in the discussion of mill arrangement and equipment. In this connection an interesting practical viewpoint was expressed at the recent meeting of the Mill work Cost Bureau by J. W. Most, vice-president of the Hurd-Most Sash and Door Co., Dubuque, Iowa, U.S.A., whose remarks emphasize such important ideas that they are published herewith:

As the mill buildings constitute a large and vital part of the factory equipment, consideration will be given first to the various types existing in our industry. Many operators have selected the one-storey building, which, with the saw tooth roof, affords an abundance of light and ventilation, while others prefer the two, three and four storey buildings. Many buildings are built with floor at grade levels, others with first floor truck high for convenience in loading and unloading from trucks and wagons, while still others are built with the first floor as high as seven feet above grade.

One Storey Type Most Efficient

In my opinion, the most efficient factory building for our line of business is the one-storey structure, constructed so that the first floor is on the level with the floor of a truck. In this type of building, the initial cost and upkeep of elevators is eliminated, and the space occupied by elevators and stairways can be adapted to productive purposes. The one-storey building also allows an ideal arrangement of machines and produces added efficiency by eliminating the cost of transporting the raw material to floors above and the returning of the finished product to the first floor. The one-storey building also permits of the very valuable feature of receiving the raw material at one end of the factory and effecting a continuous and direct course until delivered at shipping department, or store room. Those who, in the past, have been forced to contend with the frequent delaying of material during the process of manufacture, will appreciate the value of the one-storey building in eliminating this evil.

If possible, it is highly desirable that sufficient space be provided in the lumber department, so that lumber sheds and dry kilns can be placed to advantage and lumber carriers employed to transport lumber direct from the car to the lumber shed and kiln. The process of handling and rehandling by hand and by teams and trucks should be reduced to the minimum.

The equipment of the modern plant should include a steam plant suitable for furnishing steam for glue cookers, heat for glue room, steam for dry kilns, as well as power to generate electricity for individual motor-driven machinery and supply live steam for offices, so that in cold weather the offices may be utilized during periods that the mill may be inactive. Exhaust steam should suffice in most instances for factory heating. With modern steam facilities, it is possible to profitably dispose of the factory waste, such as sawdust, shavings, edgings, etc., and generate the current for motors at a nominal cost as compared with commercial current, especially where coal is used to produce the commercial current. If commercial current were to be used exclusively, the surplus offal would become a liability, for in many instances it is necessary to pay to dispise of the accumulation of this wastage. By employing individual motors instead of a steam driven plant the friction and load incident to line shafting is greatly reduced.

Selection of Machinery

In selecting the machinery, the type of equipment will vary according to whether odd or stock manufacture is contemplated. For the stock plant, the heavier, sturdy type of machine with individual motors for all arbors and spindles produces superior results. The manufacture of stock work is a mass production proposition, where volume is imperative and substantial machines that can be depended upon to withstand the grind of continuous operation should be utilized. While the initial cost of machinery of this nature may seem heavy, as compared with that of the lighter belt driven type, the outlay is justified when increased output is considered.

The diversified class of work of the special or odd millwork plant renders it impossible to produce a large number of units of work as compared with a stock plant and, therefore, the overhead or machine burden would be excessive in the event that the heavy

Upholstering and Trimming

Tapestry as a Furniture Covering

How this Upholstering Material is Manufactured at the Mills of the LaFrance Textile Co.—Weaving is a Fine Art Rather than a Trade

As an upholstering material hardly anything can surpass tapestry in the matter of artistic design, luxurious appearance or richness of color. Indeed by many furniture connoisseurs it is recognized as the ultimate in furniture coverings. Such being the case, it is of special interest to refer briefly to the progress that the art of weaving has made and describe how tapestries are produced under modern methods as exemplified in one of the largest and best known weaving mills.

The art of weaving is of such great antiquity and so general in its range over the entire earth that any inquiries as to its origin can be but useless, and any theory but hypothetic. Savage races, only a step above creation, have practiced it from time immemorial, and the cultured nations have vied with each

Preparing tapestry designs

other in its exercise until at the present time one of the most valuable assets of a nation is its capability to produce woven materials.

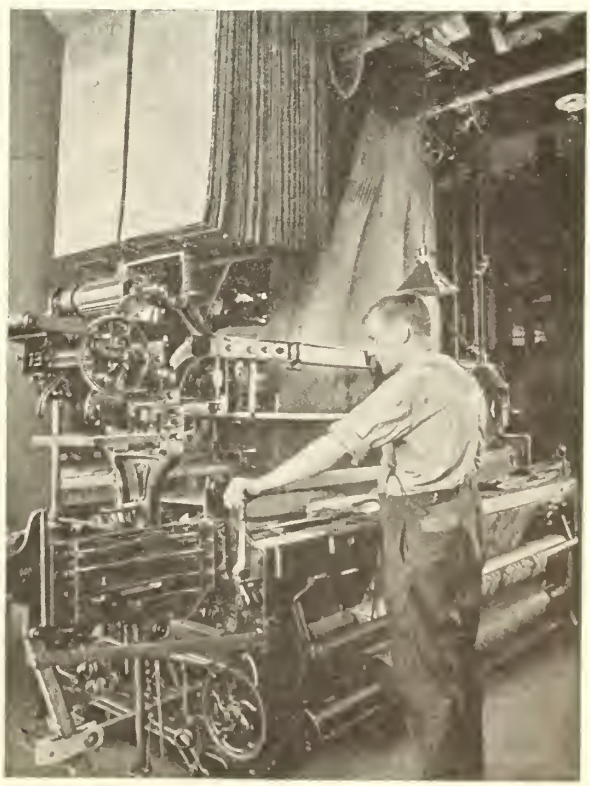
To the practical upholsterer an intimate history of the progress of the craft may, perhaps, be of only slight interest. Suffice it to say that there is a romance in the making of tapestries that appeals to the poetic, artistic and historic elements in our nature. There are records of the use of tapestry in the early classics while all down through the more modern ages, tapestry has played an important part in the life of nations. From the record of tapestry-making many facts and curious significant sidelights on history are provided.

Modern Methods of Tapestry Weaving

Tapestry weaving to-day is not the same process that was employed in bygone ages. In those times it was a household occupation where the individuality of each craftsman was evidenced in the products of

Punching the cards

his handiwork. These workmen were, indeed, real artists as only a cursory examination of historic tapestries is needed to indicate. In these modern times



Weaving tapestry. Note the cards above which constitute the pattern

mechanical methods have to some extent supplanted individual handiwork; yet withal there is in the mod-

ern weaving mill certain elements of individuality and artistic craftsmanship that give a romantic flavor to the art in spite of its mechanical background.

How the art of tapestry weaving is carried out, it is the purpose of this article to elucidate. For our purpose the mill of La France Textile Co., Frankford, Pa., is taken as being well able to indicate the processes involved in tapestry manufacture. A brief description of the processes is supplemented by illustrations indicating the various elements involved in the weaving operations and for the reproduction of which we are indebted to La France Textile Co.

The design of tapestry is drawn and then transferred on special blocked-out paper from which punched cards are punched by card-cutters. Remarkable results are accomplished through various colors in the warp and the colors of the yarn in the shuttles flying across the loom. Outside of these regular colors, various blendings and combinations of colors can

Twisting in a new warp

be obtained and very often it is difficult to foretell the results until the actual trial is made.

The setting of a loom which produces simultaneous weaving of the cloth in a range of colors and designs demands long and careful preparation. Many months elapse before a single yard of cloth can be turned out.

To the layman nothing is more mysterious than the ability to transfer the colors and designs from the sheets of paper prepared by the artist to the woven tapestry. This is where the invention of a color selector machine by a Frenchman, Jacquard, comes in. His system of punching round holes in a cardboard corresponding to the design of the artist, is what has given a mighty impetus to the tapestry industry.

Then the different yarns colored exactly to meet the ideas of the colorist are strung on the loom and controlled by the Jacquard system. These long ends of yarn are prepared on beaming frames, sometimes each thread being over one thousand yards long, and it is a special craft of its own to be able to lay the warps, the experienced beamers requiring many years of practice.

When these warps are used up, another beam takes its place, and to twist the threads in requires

MARIETTA WOOD AND METAL FINISH SPECIALISTS

Marietta Paste Wood Fillers

The largest talking machine manufacturer in the world uses Marietta fillers exclusively, the contract running about a carload a month.

Marietta fillers are made from the highest grade silex, linseed oil and special binders.

They have been in use in the furniture manufacturing field for a quarter of a century and can be depended upon to give highest satisfaction.

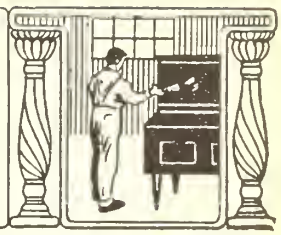
THE FINISHING ROOM



Cutting Your Rubbing Costs

Pay Strict Attention to the Woodworking and Sanding Operations—Often Possible to Save One or More Coats of Varnish

From fifty to seventy-five per cent of the rubbing costs can be saved through stricter attention to the preparation of the foundation for the varnish coats. This means a worth-while saving, for the rubbing operation usually requires more time than any other one finishing operation. As compared to filling the time is about four to one.

To the manufacturers and finishers the little details which require attention in preparation of the surfaces to be finished and in the earlier finishing operations may seem like unimportant trifles. It is said that perfection is made up of trifles, but perfection is no trifle. This attitude is seen again where an attempt is made to cut the cost of an article by purchasing a cheaper grade of varnish or cheaper grades of finishing material, overlooking the fact that the appearance and saleability of the article depends largely on the finish and that a well finished article often commands a premium over a poorly finished one. From this it will be seen that a few cents saved in the cost of the finishing material may mean a reduction in value, or at least in the selling value, of several dollars.

Varnish Not a Filler

But to get back to the question of reduced rubbing costs, we can accept as a fundamental principle the fact that varnish cannot be considered a filler in any sense of the word, and as a consequence, should never be depended on to fill depressions or to overcome any inequalities which may exist on the surface to be finished. Then to secure a suitable foundation, which means a smooth level surface free from depressions and inequalities,, for the varnish coats, it is necessary to go back to the woodworking operations and see that they are performed properly.

In the case of the planer, the knives should be sharp at all times and the shavings exhaust system must be able to carry away the shavings as fast as they are made. Depressions made by shavings getting under the cylinder knives, may be sanded out but the wood underneath has been compressed and is sure to expand when the stain is applied. This causes high spots on the stained surface which gives a considerable amount of trouble.

Needless to say, the sanding operation is extremely important, particularly the final sanding and cleaning. By paying closer attention to the surface produced by the various sanders it is often possible to eliminate one or more varnish coats. This is a point well worth considering. One coat of varnish upon a smooth even surface, that is one fully prepared, will give as good a finish as three or four coats upon a poorly prepared surface, with this advantage that in the case of the single coat on the good foundation the rubbing will likely be about one-fifth of that required on the heavily coated surface, with better results.

Viewing the various steps of the work in the light of their effect on the final varnishing and rubbing operations the filling of the pores takes on added importance. A little extra attention to the filling, such as sure that the filler is set before being worked off or particularly, that it is not rubbed out of the pores, will not only often save one coat of varnish and cut down the rubbing time to perhaps one quarter or one-fifth but will ensure a finish that is free from pinholes and similar faults.

One other suggestion is that when a piece or part is encountered, either in the final sanding or early finishing operation that is not in good condition, either rough, wavy, dented or sub-standard in some other way, it is far more profitable to throw it out without putting any more labor and expense on it than to put it through all finishing operations only to discard it finally or have to send it out knowing that it is not up to the mark. As intimated the finish is too important and its effect on sales and value is too strong to be neglected or considered in a haphazard manner. Perfection should be the ideal and goal and as far as finish goes perfection is made up of such trifles as have been outlined here.

The Cause of Green Cast on Mahogany Finish

Usually Attributable to Improper Filler and Stain or Manner of Applying Them—Varnish Sometimes Responsible

A producer of phonograph cabinets recently mentioned to the "Canadian Woodworker" the fact that he has been having considerable trouble of late with the finish of his mahogany, a greenish tone being very noticeable on one certain line of cabinets, and he asked us to give him some idea of the cause of this undesirable effect. This greenish cast on mahogany varnish finish seems to be very prevalent and a number of reasons have been advanced as to its cause, which are explained by various authorities and enumerated below.

The greenish tone, which appears to be fairly prevalent in dark finished woods, is usually attributed at first thought to the varnish, because it does not show up until the varnish coats are applied. The assumption, however, that the varnish is the sole cause of this defect is not correct, for probably in the majority of cases the varnish is not directly responsible for the greenish cast, but merely brings out defects in the condition of the stain and filler undercoating. It is a fact, of course, that some varnishes tend to affect the uniformity of the finish. Some of the darker colored varnishes, for example, have this greenish

effect in themselves when viewed in a reflected light. This is particularly true when several coats are applied. If the finish can be produced with less material, there is quite likely to be a complete absence of green. What will also help the defect in such a case is the use of a paler varnish or some tint color. One authority who has done some experimenting along this line also states that the use of too fresh a varnish tends to produce a greenish cast, since chemical action has not been completed in the varnish. The use of a pale, aged varnish absolutely overcomes this tendency.

If varnish is applied by a spray, there is a possibility that moisture may be playing a part in the development of the green color; certainly milky varnish indicates moisture. In such a case the gaskets of the compressor possibly leak, or the spray machine is held too close to the work.

Improper Filler and Stain

Regardless of the varnish, its color, price or the way it is manufactured, poor filler or improper use of filler and defective handling of stains may be productive of the greenish cast. One authority states that he has seen several cases where the shellac substitute coat or shellac coat has cut into the filler and stain in such a way as to take up some color and create the conditions which brought the green cast when the work was finished. This can be corrected by thoroughly analysing the staining and filling process to determine what must be done in the way of changing the stain or filler or the method followed to avoid the difficulty. Too much black, for example, in the filler and stain will produce this green cast every time.

Stain that is too strong will often produce a greenish cast if the excess color is not removed. A piece of cheesecloth dampened with alcohol and sponged over the work after it is sanded is quite effective in removing the surface stain. However, the only way to prevent this condition is to see that the color is thoroughly dissolved and the stain strained before application. Half an ounce of powdered alum to a gallon of stain has been found to be very effective in bringing the undissolved matter to the surface and aiding the straining.

Improper sanding is also stated to be a cause of green cast—especially sanding varnish that is not properly hardened or using too coarse a sand paper. The result is a grayish effect which becomes green on several re-coatings. There is another cause which is dependent on the result of the chemical action between the stain or filler and the veneer glue. This occasionally develops on dark finishes a cloudy or smoky effect which, when viewed in reflected light, shows decidedly greenish. With thin veneers, the pores are partly filled with glue when the work comes to the finishing department and so to a certain extent finish is built up on glue instead of wood.

The proper handling of paste filler in the package and in the pot is said by one authority to prevent one cause of greenish cast. The top layer of filler in an open kit or barrel will harden and oxidize in the same way as it hardens when properly placed in the pores of the wood. Such partial oxidized filler is bound to give poor results on the work and is difficult to rub off clean. The proper thing to do is to prevent the exposure of filler to the air by protecting this surface in the open package. Unless filler is rapidly used, it should be supplied in metal packages and not in wooden barrels as in that case some of the oil binder is absorbed by the wood and leaves the filler with an inadequate amount of binder. Such filler is harder to clean off and an excess filler usually produces a greenish cast on varnishes.

Will Decorated Furniture Survive?

Will Lose Favor if the Finish Is Not in Good Taste—Lack of Artistic Judgment and Finishing Knowledge Is Detrimental—Enamel Decoration, Stippled Finish, Polychrome and Japanese Lacquer

By W. C. L.

Decorated furniture will survive because of its merit, especially when executed as finely as some of the earlier masters, such as Adam Brothers, or as even the more crude but quaintly painted furniture of the French or Italian peasant style. The so-called painted commercial furniture, having too little regard for harmonious decoration and color, loses favor and there is but little place for its use in average homes other than in possibly sun or breakfast rooms. Refined Canadian or American tastes call for a harmony of color, and not so great a contrast of color in home decoration or dress as in a country like Italy where the very atmosphere is more luminous and colorful.

The commercial life of decorated furniture has suffered through the lack of artistic knowledge and appreciation on the part of the manufacturers—meaning also the men actually employed in the decorating and finishing departments. However, the ultimate effect is entirely dependent on the actual worker, no matter what the desire or ambition of the manufacturer may be.

The mixing of colors; knowing the process of antiquing effects on woods or enamel surfaces and the innumerable requirements of more artistic judgment are too little appreciated, studied or practiced by a finisher. Experiments in finishing departments offer much that creates new interest for him and gives knowledge that is of vital interest to the manufacturer. To know that French carved styles require but a shellac and wax finish to be more nearly correct; to know that practically every period originally had an individual finishing effect which can be reproduced successfully in a commercial way is appreciating one of the big factors that makes for individuality in many high grade furniture lines.

Importance of Finishing

At no time in the furniture manufacturing industry is finishing as important as to-day. Simple

Fifty Years as Manufacturers of Good Sandpapers

An Appreciation

To those who have so largely contributed to the success of Herman Behr & Company in its half-century of existence, we wish to express our gratitude.

To our Customers for their recognition and support and our Competitors for their progressiveness—invaluable incentives to merit the good-will of all.

To our Employees—loyal and staunch, many of whom have been with us over forty years.

To our Founder for his ideals, inspiration, and steadfast adherence to the highest standard of quality and service during his entire fifty years as head of our Company.

And to all those who have helped create the enviable reputation which the Company enjoys today, we are grateful on our Fiftieth Anniversary.

HERMAN BEHR & CO., *Inc.*

designs with careful selection of veneers and woods, together with a clean, clear finish are attempted by nearly all manufacturers but to finish a design containing a few colors of veneers and overlaps into a beautiful harmonious whole requires considerable skill and gives a manufacturer latitude for individuality. To follow this last effect and introduce black ebonized effects and antiquing shows the trend of thought in some high grade dining room and living room lines which will be followed by medium grade manufacturers soon.

The recent introduction of Span-Umbrian furniture shows an unusual example of skill in finishing. Few finishers would have the initiative or ability to create such a rare color scheme. Designers who have studied antique models of all the old schools, or have travelled extensively, readily grasp the sense of color and its application to various styles. They should be more and more called upon to pass judgment on proper coloring. More than that, they should be able to actually execute and supervise the sample work. They should uphold the artistic and more scientific points of construction and design. They should know much of chemistry, and should know the ingredients and effects of water or oil stains, varnishes, shellacs, etc., and keep posted on all the new finishes.

Finish Must be Right

Most manufacturers concentrate all efforts on merely turning out quantities of furniture and have little sympathy or regard for the likes or dislikes of the ultimate purchaser of his production. Some consideration should be given the fact that women buy and furnish most of the homes. With two pieces of furniture involving the same expense in manufacturing, the one having the greater amount of design and character naturally commands the greater selling price. Competition on mediocre characterless furniture is already too great. Here there is too much price cutting in normal times to see how little the article can be sold for. Individuality in furniture permits profits as it eliminates competitive buying through comparison. Furniture is not bought merely because it is either Chippendale, Hepplewhite, or of other periods, but because the design and finish is a happy, likable combination. Periods that do not sell either are not fully explored or cannot be made livable or commercial.

The Use of Overlays

The old schools usually inlayed broad bands or panels of veneer but a more recent development that has not been fully explored in a commercial way is applying an overlay of more choice and closely grained wood, showing contrast in color. Overlays on walnut or mahogany of Mexican cedar burls, ash burls, oak or English oak, walnut butts or burls, or bird's eye maple burls produce unusual and inexpensive effects that may either be ruined or enriched by proper finishing. These veneers are very porous and invariably finish either too light or too dark without extra attention. More filling or staining is necessary. However, walnut butts on mahogany or walnut are very pleasing with the usual stain and finish employed in the regular manner. Manufacturers of finishes willingly co-operate with the furniture makers to experiment and furnish proper wood or enamel colors that could not otherwise be secured when an expert finisher is not employed.

The tendency in high grade dining and living room furniture is to merely use light varnish, shellac or wax finishes. It requires extra care in the preparation of the wood surfaces but is more durable and practical.

The Italian style now being revived offers rich opportunity for securing rubbed off effects on carved or plain mouldings, sparingly carved rosettes, panels or turnings. Decorated furniture will always survive when the decorators show individuality. There is no medium in recent years that has given them such scope, especially when manufactured or finished under their supervision. This sometimes calls for special designs and some unique finishing effects wrought by enamel decoration and striping; stippled finish antiqued; polychrome (meaning many colors) or red, yellow blue or black Japanese lacquers.

Enamel Decoration

The primary coat of enamel is two applications of white lead undercoating, preferably the color which will be used on the outer coats. Ordinary white enamel mixed with the primary colors will secure every shade or effect one desires. The striping or decoration should be done in oil colors, after which a protective coat of white maple varnish should be applied. There is no limit to the possibility of new and beautiful combinations.

Stippled Finish

Stippled finish is having the second and third white undercoating brought to such a consistency that by applying a long, stiff-haired brush uprightly, the surface is made irregular like stone effect. A thin varnished coat of whatever color is desired is applied, after which sandpaper should rub off only the higher points of the stipple. This gives the two-color effect of the body and top coats. With added decoration and striping in various colors artistic effects are given. A preservative coat of maple varnish should also be applied.

Polychrome

Polychrome is usually applied on mouldings, turnings or carvings. The principal danger in this and practically all decorations is not keeping them properly subdued. The colors are ground in Japan. Chrome yellow can be used as a body color; Prussian blue with a little black, red or green added to give high lights. When nearly dry a porous bag,

Set Outside Your Varnish Room

The money a Nichols Paint and Varnish Dryer saves will pay for the equipment in one year.

This is not a wild statement but one we have proved time and again to manufacturers in practically every branch of the woodworking industry.

The Nichols Vertical Paint and Varnish Dryer is a complete unit of fan, motor, heaters, air compressor, with automatic humidity and temperature controls. A new rotary, humidifying air washer which eliminates all dust and dirt and does away with all spray heads, pump and connecting piping.

The equipment is manufactured in sizes suitable for all requirements.

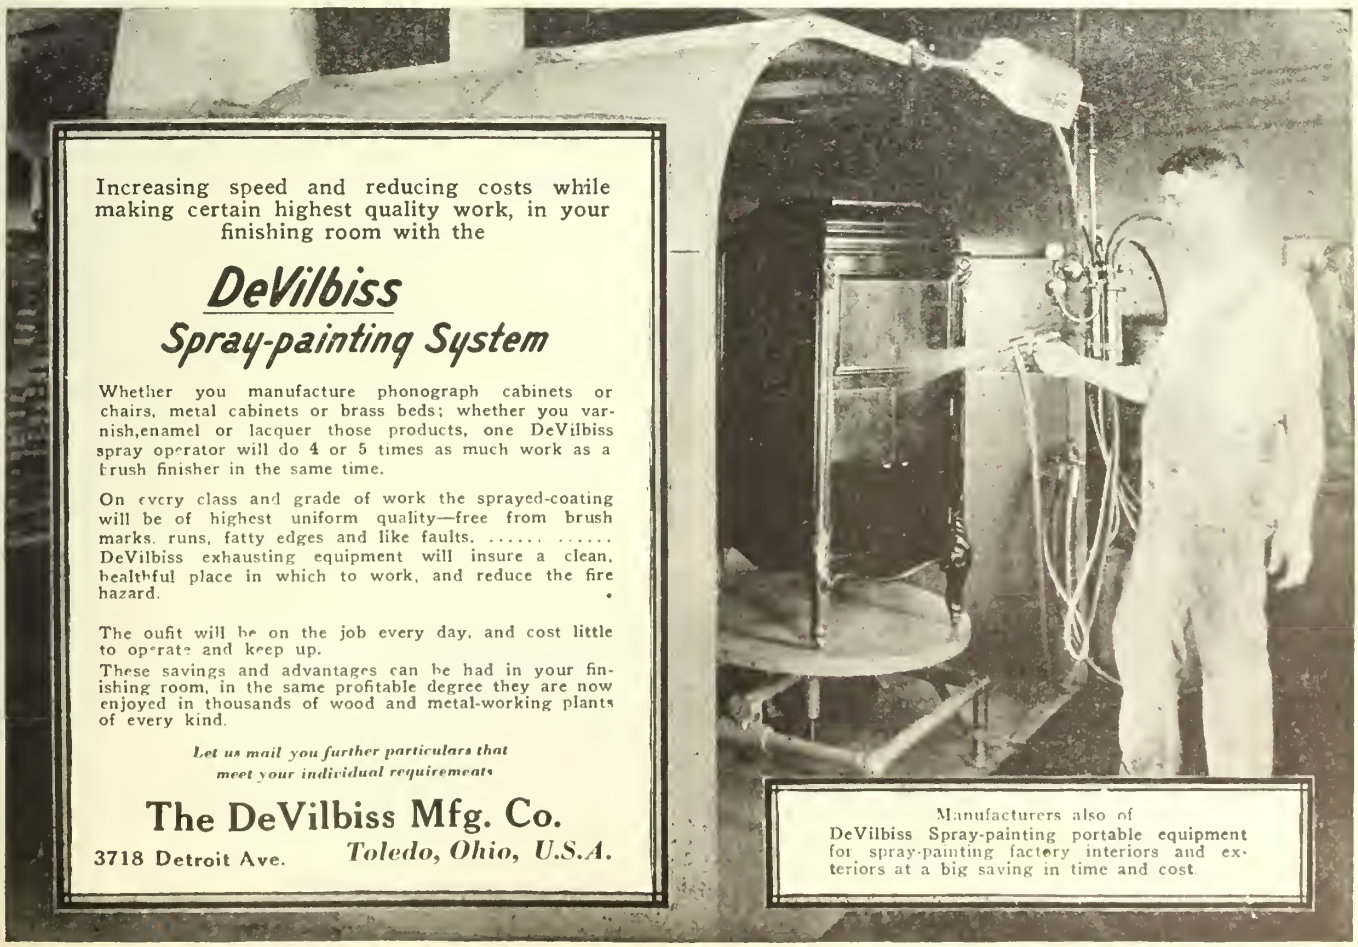
Let us analyze your particular needs and quote prices on same.

A. S. NICHOLS COMPANY

Aeolian Hall

33 West 42nd St., New York City

Manufacturers of dryers for lumber, veneers, glued stock, varnish, paints, enamels, etc.



Increasing speed and reducing costs while making certain highest quality work, in your finishing room with the

DeVilbiss
Spray-painting System

Whether you manufacture phonograph cabinets or chairs, metal cabinets or brass beds; whether you varnish, enamel or lacquer those products, one DeVilbiss spray operator will do 4 or 5 times as much work as a brush finisher in the same time.

On every class and grade of work the sprayed-coating will be of highest uniform quality—free from brush marks, runs, fatty edges and like faults. .... DeVilbiss exhausting equipment will insure a clean, healthful place in which to work, and reduce the fire hazard.

The outfit will be on the job every day, and cost little to operate and keep up.

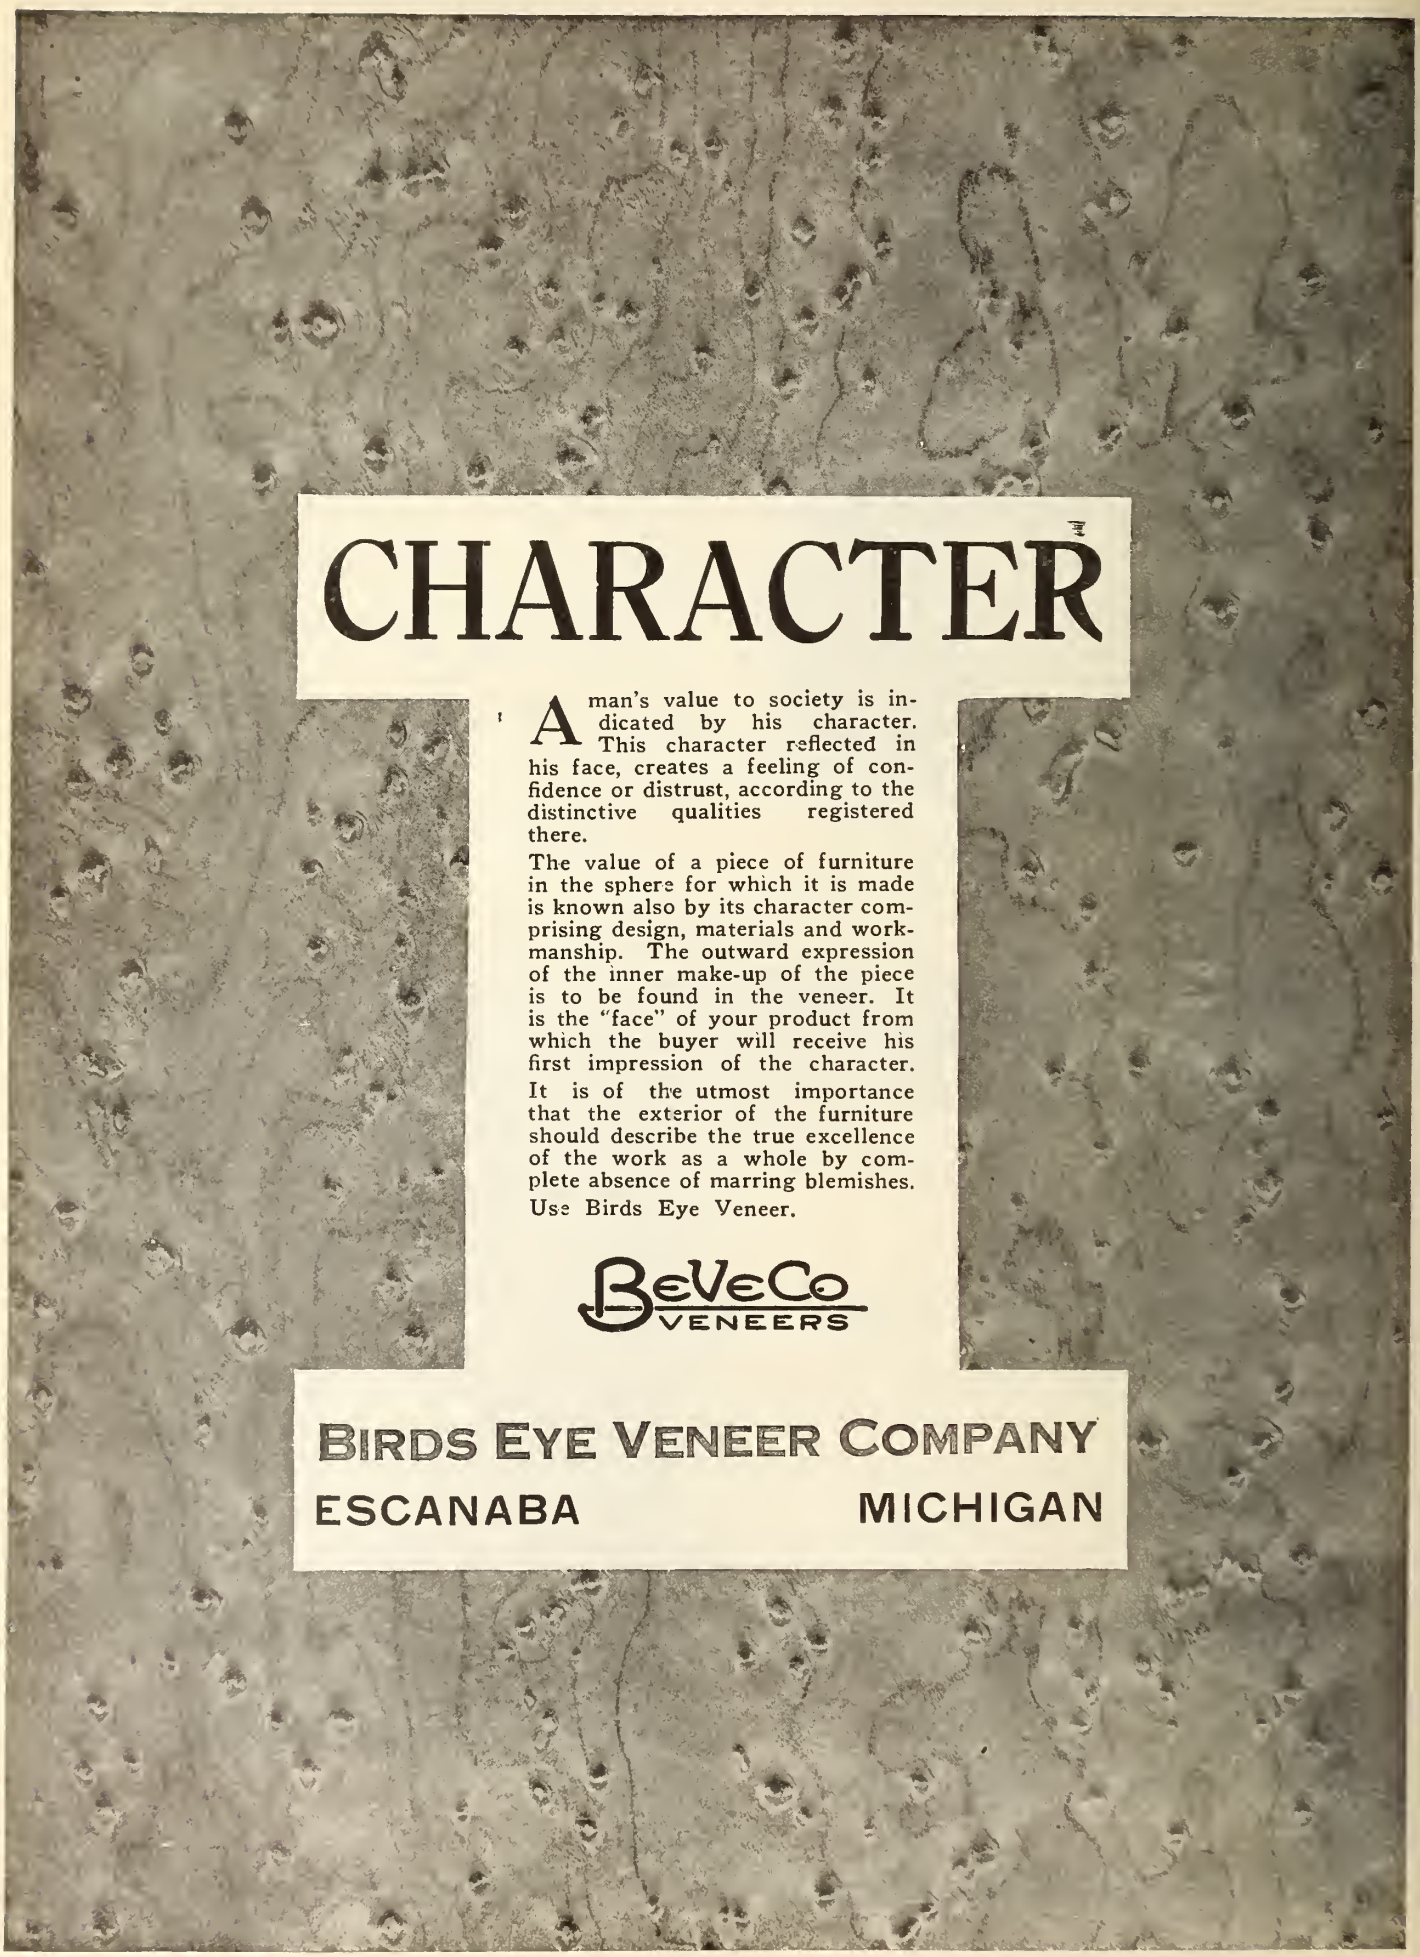
These savings and advantages can be had in your finishing room, in the same profitable degree they are now enjoyed in thousands of wood and metal-working plants of every kind.

Let us mail you further particulars that meet your individual requirements

The DeVilbiss Mfg. Co.

3718 Detroit Ave. *Toledo, Ohio, U.S.A.*

Manufacturers also of
DeVilbiss Spray-painting portable equipment for spray-painting factory interiors and exteriors at a big saving in time and cost.



CHARACTER

A man's value to society is indicated by his character. This character reflected in his face, creates a feeling of confidence or distrust, according to the distinctive qualities registered there.

The value of a piece of furniture in the sphere for which it is made is known also by its character comprising design, materials and workmanship. The outward expression of the inner make-up of the piece is to be found in the veneer. It is the "face" of your product from which the buyer will receive his first impression of the character.

It is of the utmost importance that the exterior of the furniture should describe the true excellence of the work as a whole by complete absence of marring blemishes.

Glue Room Economy and Technology

Minimizing Heating Losses—Wastefulness Due to Bacterial Decomposition — Need for Glue Room Cleanliness

By R. H. Bogue*

(Concluded from the June issue)

If the evaporation of water from the glue which takes place on heating were made up by occasional additions of water it would very soon become apparent that the glue rapidly became thinner as heating progressed until it was altogether too watery to apply. In general, this decrease in viscosity or spreading capacity escapes attention and remains quite unobserved because of the fact that the same heat treatment which is responsible for it also results in evaporation of the water and consequent concentration of the glue in the solution.

One other point in this connection is worth attention. The loss due to heating has been found to be proportional to the temperature, increasing rapidly as the temperature rises from 140 degrees F. to the boiling point. The figures which have been given are based upon a heating at 176 degrees. But very often, where the temperature is uncontrolled, much higher values are reached, and not infrequently in fact, the glue is actually permitted to boil. A very few hours of boiling is sufficient to render the glue worse than useless for high- class joint or panel work.

It is obvious, therefore, that prolonged heating of a glue results in both a loss in strength and a decrease in the covering capacity. The latter, however, is concealed through evaporation of the water, and the loss in strength is usually unobserved on account of the excess in strength of the glue as bought above that necessary in the operation. The higher the temperature the more rapidly will depreciation take place.

The losses referred to may not be made good by the addition of water to make up that lost by evaporation, for the product would be too thin to spread properly, and would result in a weaker joint. All losses due to heating may, however, be minimized by dissolving only that amount which will be used immediately, and preventing the temperature from rising above 140 degrees F.

As soon as these simple principles are efficiently applied, a lower margin of safety may be confidently employed, which means a less expensive glue, or the same glue at a greater dilution, may be employed with equally uniform and satisfactory results.

The unsanitary appearance of the glue room with its disagreeable stenches is proverbial. It has been taken as a matter of course for so long that it is too often believed a necessary adjunct to the use of that substance. Glue pots in some places are never cleaned. The floor becomes covered with a gradually thickening layer of the spillings. But glue is an animal product and subject to bacterial decomposition. What wonder then, that the pots, the room, the new work, all imbibe the characteristic putrid odor! Probably the greatest number of complaints which are made by glue consumers to the dealers and manufacturers are based upon the affirmation that the glue in question is "sour." Investigation shows the pots and kettles to be coated sometimes inches thick with glue in an active state of decomposition that has been accumulating for months. It is doubtful if these same men would expect that sweet milk could be poured into cans containing decomposed milk without itself becoming sour very quickly, but they appear not to have applied that reasoning to the glue pot.

Putrefaction of glue takes place very rapidly at the temperature which obtain in the glue room. A sweet glue allowed to remain for a few hours in contact with decomposing glue will become sour, but that indeed is not the worst or only objection to permitting of such practices. A sour glue is not merely a glue that does not smell good, but it is a glue that

Efficiency in the Glue Room

The necessity of an intelligent control of all operations in the glue room, if efficiency in this department is to be attained, is the lesson conveyed in the three articles, of which the last appears in this issue, on "Glue Room Economy and Technology," by R. H. Bogue. Glue users in the woodworking industries are not always aware, we are convinced, of the wasteful and unnecessary abuses to which glue is frequently subjected, nor have they a good working knowledge of how the material should be handled to the greatest advantage. In these articles Mr. Bogue has aimed to explain the simple principles of glue technology, to the end that glue room procedure may be intelligently and efficiently regulated. Among other points the importance of water proportioning and temperature control is especially emphasized, while the wastefulness of permitting bacterial decomposition and the enormous monetary loss resulting from such practice is demonstrated. Taken all in all, these articles form an interesting, practical and timely treatise on glue room practice. It will be of interest to note that in our next issue Mr. Bogue will commence a further series of articles covering the conditions affecting the adhesion strength of glue and the methods of making adhesion strength tests

*Industrial Fellow of the Mellon Institute of Industrial Research and Research Chemist for Armour & Co., Chicago.
This article represents a part of the section of the "Glue as an Adhesive" in the writer's forthcoming treatise on "The Chemistry and Technology of Gelatin and Glue," to be published by the McGraw Hill Company of New York in the Summer of 1922.

has suffered a chemical change in its constitution. That change is an hydrolysis, slightly different in the nature of the cleavage products produced from hydrolysis by water, acids, alkalies, or enzymes, but nevertheless an hydrolysis, or a breaking down of the gelatin molecule. This decomposition results in an alteration in the properties of the material. The viscosity, the jelly consistency, the joint strength obtainable, are all greatly reduced. Futhermore, the action of the bacteria does not stop upon the application of the glue to the joint, but continues even after drying out. This means that a failure of the joint is very apt to result sooner or later. It makes no difference whether a high grade or a low grade product is used at the start, the contamination with the decomposing material will in a few hours reduce it to a low grade, and reduction in strength will continue in the joint.

Decomposition is a Serious Matter

The loss in dollars resulting from such practice is unquestionably enormous, not to mention the harm done to the house by an injured reputation due to failures in their glue work. Just as in the case of prolonged heating, a high grade glue may be bought, but by the time it is actually put into service it may have been reduced to a very low grade. But while the heating loss ceases as soon as the glue is applied, this is not the case with the decomposed glue, and the latter may, therefore, be productive of even more serious loss than the overheated material. This fact is certainly indicated, if not proved, by the experiments of the United States Forest Service previously referred to. They found that the loss in strength and viscosity sustained by maintaining glues at 104 degrees F. for a number of hours was actually greater than that sustained by maintaining them at 140 degrees for the same period. At the latter temperature the bacteria are inhibited, if not killed, so that the loss in strength observed is due entirely to ordinary water hydrolysis. But at 104 degrees the bacteria are very nearly at their optimum temperature for activity. The water hydrolysis is unquestionably greater at the higher temperature, so the greater loss in strength and viscosity at 104 degrees is due directly to the decomposing action of the bacteria, and to nothing else.

Thorough Cleanliness is Cure for Bacterial Activity

The cure for this disastrous activity of bacteria is very simply to keep the glue pots, kettles, brushes, and all other articles that come in contact with the liquid glue, thoroughly clean. There is no remedy that may be applied to a decomposed glue to again bring it into a sweet condition, and all glue that has become sour should be discarded at once and without regret. Attempting to use it up will bring even greater loss than the price of the glue thrown out. The glue pots and kettles should be drained into a clean container each night, and should be thoroughly cleaned before used the next day. The brushes, stirrers, thermometers, hydrometers, and other implements should likewise be well cleaned. The work benches and floors should be scraped free of all glue that has accumulated on them during the day. By following these simple precautions bacteria will be unable to gain sufficient headway at any time to damage the glue, while the general appearance and odor of the glue room, and the health and morale of the workmen will make such an alteration in glue room technique a decidedly worth-while undertaking.

One further point in this connection. Glue is exceedingly sensitive to the moisture conditions in which it is stored. Occasionally glue will be stored in damp cellars where a considerable absorption of water will take place in the glue. Under such conditions it may happen that a sufficient amount of water may be taken up to enable bacteria, molds, or other micro-organisms to attack the material. Molds especially grow under such conditions, and good glue may be completely spoiled by the decomposition effected by them. On melting these glues the viscosity will be low, the odor will be strong and sour, and joints made by their use will be weak. An excessively dry atmosphere is not to be recommended as the glues become brittle but it is to be preferred to the damp conditions of storage.

Overcoming Public Prejudice Against Veneer

Play up the Word "Plywood" Instead of "Veneer" —Create Interest by Educational Work

Public prejudice against veneered products caused by a lack of appreciation of the significance of the term "veneer," is an important factor in hindering the sale and use of veneered goods, in the opinion of Geo. N. Lamb, secretary of the American Walnut Manufacturers' Association. Addressing the National Veneer and Panel Manufacturers' Association at their Chicago meeting last month he had this to say in urging an educational campaign directed towards developing public confidence in veneer and veneered products:

As I see your problem it is comparatively simple. You want to sell more veneers and plywood. To do so you must create consumer demand rather in your case, or overcome consumer resistance. According to the dictionary and to the belief of most people the word "veneer" means something shoddy, make-believe, or a process to cover up something inferior. At the "Better Homes Exposition" I have come in personal contract with thousands of furniture owners in various large cities and have had the painful knowledge thrust upon me that the word "veneer" is hopelessly "in bad" with the public. We know it isn't true, we know that veneers have a most worthy place in wood construction, and that plywood, both structurally and artistically, is a superior article. What you know and what the public thinks, however, are two distinctly different matters.

Advertise Plywood

Your problem is to put both veneer and plywood where they belong, by educational work. This can be done at a reasonable cost and profitably by education on "plywood," "built up panels" or whatever you decided to call the product. It cannot be done by talking "veneers." The pretty stories of the history of veneers make the veneer man feel good but they won't sell veneers to the public. It will be infinitely easier to sell to the public a new word like "plywood" than it will be to overcome a universal prejudice that exists against "veneers." The word "veneers" is hopelessly dammed and it would take a generation

to a full appreciation of its advantages. On the other hand the word "plywood", where it is known, is favorably known. Its development during the war caused a lot of people to hear of it and learn its value. Building on the plywood idea you can sell it to the public, and if plywood goes over then gradually veneers will come again into their own. It is human nature to tell others when you get a new idea. Everyone likes to pass on timely bits of real information.

Public is Prejudiced

This trait can be utilized to sell the public on "plywood." The same trait makes the well established resistance to "veneers" positively hopeless. As a concrete example—I have shown fine walnut room paneling and literally talked it to thousands. The first expression is usually "My! isn't that beautiful? I always did like walnut." The next expression is usually an interrogation. "Is it solid or only veneered? At first I answered "yes" and enthusiasm cooled and the visitor passed on. After various experiments I found that I could not hold their interest by explaining that the panels were built up plywood. I explained the core, the crossbanding and the figured face. I briefly pointed out the superiority of these panels and the word "veneer" finally was dropped entirely from my vocabulary— it would not do. It raised a mental wall to the acceptance of my message.

New Life for the Veneer Manufacturer

The Merger of the National Veneer and Panel Manufacturers' Association and the Plywood Manufacturers' Association will have Important Effect on the Future of the Thin Lumber Industry

The final ratification of the merger of the National Veneer & Panel Manufacturers' Association and the Plywood Manufacturers' Association was accomplished at a meeting held in Chicago on June 21st and 22nd, at which the new scheme of co-operation was thoroughly discussed and plans were outlined for the future welfare of the new organization. The April issue of the "Canadian Woodworker," referred to this all-important move among the thin lumber manufacturers and briefly indicated the scope and policy of the combined organization. It was pointed out that the intention of the organizers of the merger was to

H. Brooke Sale, the president of the National Veneer and Panel Manufacturers' Assn.

maintain the individual identities of the various interests involved in the veneer and plywood industry, grouping them together, however, into one strong powerful association which could handle matters of common interest. Provision is made for subdivision into groups according to the various kinds of wood involved, methods or other desired basis of manufacture, each group electing its own chairman who automatically becomes vice-president of the parent body.

A considerable part of the joint meeting in Chicago was devoted to an explanation of the new scheme, Commissioner M. Wulpi reviewing the conditions that had brought about the merger of the two associations, and outlining the plans on which the work was to be conducted. He made a report of the membership in the three classes as fixed by the by-laws, viz., manufacturers, jobbers and supply manufacturers, stating that 88 plants were on the role. Mr. Wulpi reported that the complete amalgamation of the associations had been consummated, the machinery of the new organization had been set up, and everything was in readiness for a display of new life and vigor.

The delegates were thoroughly convinced of the possibilities of the new organization after hearing the very effective address of the president, H. Brooke Sale, whose message was replete with optimism regarding the National Veneer and Panel Manufacturers' Association under the new scheme of organization. Speaking first of conditions in the plywood and thin lumber industry, Mr. Sale said:—

"It is not my intention to bore you with a lot of my ideas of what is going to happen in business, for with Babson, Brookmire, and Hoover gathering statistics and disseminating it, the first two, I imagine, at an enormous financial benefit for themselves, it would be rather presumptuous, in my opinion, for a business man who does not maintain a statistical department to attempt to advise you as to what is going to happen in the future.

"However, by deduction, we all must feel that we are on the verge of a long, strong prosperous period, not one such as we experienced in 1919 and the early part of 1920, but a logical, healthful prosperity. Those who have prepared during the period of physical, financial and moral reconstruction for what is to come, those who have fortified themselves with every available method of economy, will fare best, and be prepared for the final reaction to depreciation which will inevitably come when the point of saturation is reached. . . ."

Scheme of Organization is Logical

Mr. Sale then proceeded to allay the fears of those who were inclined to be dissatisfied with the merger. "Personally," he said, "I am thoroughly of the opinion that we are on the right track, and those who think

For high-grade rotary cut veneer, that is smooth and evenly cut and dried by mechanical means to any percentage of moisture desired.

We also operate large band mills where all kinds of southern hardwood lumber is cut from our own tract of timber in the very heart of the Saint Francis Basin District, Arkansas.

PENROD-JURDEN COMPANY

A Name that Should be on your Enquiry List for both Veneer and Lumber

Mills at Helena and Penjur, Ark. General Offices: Memphis, Tennessee.

Exclusive Manufacturers American Walnut Lumber and Veneers

IT is generally conceded that this will be a bigger year than ever for Walnut Furniture and Interior Trim, and we are ready to supply the demand.

Your co-operation in early placing of orders will be of material assistance in helping to avoid an abnormally strong market which always reacts in higher prices.

We do not wish to see higher prices. Co-operation is the life of business at any time. At this time particularly you will find us as producers ready to co-operate in every way possible with consumers to ensure a steady supply of Walnut equal to the demand.

May we know your requirements early?

New Life for the Veneer Manufacturers

(Continued from page 82)

to the contrary are wrong in that if they will understand the scope of the groups and the proper functions of the National Veneer and Panel Manufacturers' Association, they will see wherein it is as widely thought out an association as there is in the woodworking industry of to-day. What can be more logical than to bring together the various manufacturers and processes of manufacture for general discussion and sociability, and to organize into groups each of those who consider it to be an advantage to do so, either by process of manufacture, kind of wood or any other method which they collectively might decide upon, and they in turn to discuss with one another, function, and organize properly for such activities as concern their particular group . . . . . It is not the intention of the National Veneer & Panel Manufacturers' Association, so far as is possible, to decide to do anything other than attempt to knit together the various interests into a common interest in such functions as are common to us all, and to subdivide our work separately into those parts of the industry as you may determine for yourselves to be logical and to your advantage."

Importance of Cost Work

Mr. Sale outlined some of the work that the organization would have to interest itself in, pointing out that it had certain functions which it would be possible to carry on with the groups organized under it, which would not be possible of accomplishment by individual groups. He referred particularly to traffic matters, costing, and publicity and trade extension. Very particularly did he emphasize the need for the development of a thoroughly satisfactory costing system for the veneer industries. In this connection his remarks follow:—

"Another very important function, valuable statistics, and methods to which we have fallen heir through the courtesy of the Plywood Association is a logical costing method. They have the machinery set up, and reports made, and a very competent cost engineer for the costing of our industry, and it only remains for the rotary manufacturers, and such other groups as may form and wish to take advantage of this, to have established in their industries an intelligent method of costing at a nominal expense.

"We (meaning those with whom I have been associated in the manufacture of sawed and rotary cut thin lumber) have held the opinion for a great many years that costing could not be accurately determined in the reduction of forest products into lumber and so-called veneer, owing to the fact that it is impossible to accurately determine the value of a log until it is manufactured.

"We had our eyes opened recently through an audit made by the Inventory Auditing Division of the Internal Revenue, stating to us that they had not found it possible to obtain costs in two industries. Now, you will be surprised to know what these industries are. The one is the packing industry, and the other is the forest products industry.

"Regardless of this statement, such industries as Armour, Swift, Cudahy and others who are producing such a large percentage of our food have certainly not gone on all these years without a method of costing as you may well know, but we in our industry, taking it as a whole, have been grossly ignorant of our cost, and even though we should be not able to get a costing system which would be absolutely accurate to the minutest detail, yet it would be far better to know that when a commodity was sold at a certain price it would yield a profit.

"We are grossly neglectful in our industry in not having established a uniform costing system, and the time is not far distant when those who are properly equipped with a costing method will have come to the end of the road, because our vast forests are being surely consumed, and wasted with a prodigality equalled by no other nation in the history of the world. As a whole, our industry is as ignorant of costs as could be possibly conceived, and surely when that time arrives when prosperity will have been considered as past, and we reach the cycle known to the statisticians as "liquidation" which comes just prior to readjustment, then and then only, will those who are properly equipped understand that they have wasted their time and energy and will realize but a small percentage of the book values which they have set up.

"Let us not be like the ostrich and stick our heads in the sand and think that the storm is past, or that we can stick our heads in the sand at any time and let the storm pass, but let us build a properly-constructed storm-proof cost accounting system so that we may not be surprised by an adverse statement at the end of our inventory period and may be able to anticipate our losses, which would otherwise occur."

In conclusion, Mr. Sale urged the members to put their shoulders to the wheel and push the new organization wholeheartedly. "I feel," he said, "that we certainly will have missed an opportunity, yes, even shown our gross ignorance of things that are happening about us, if we do not get wholeheartedly behind the National Veneer and Panel Manufacturers' Association and make a stand in our subdivision of the industry equally as high as any other association in any other business, and I am thoroughly convinced that we are now so connected, through Mr. Wulpi, our commissioner, as to be entered upon a period of association activity such as we have never realized or known."

Publicity Campaign Abandoned

Another important matter which received attention at the meeting was the question of the national publicity campaign, regarding which Commissioner Wulpi made a report. The discussion disclosed the fact that under present conditions it was not thought advisable to continue the effort, and a refund in full of all contributions was ordered. An understanding was reached that as soon as matters opened up the campaign would be re-opened and pushed vigorously.

Interesting addresses were delivered by George N. Lamb, secretary of the American Walnut Manufacturers' Association, and F. F. Fish, secretary of the National Hardwood Manufacturers' Association. The subject of the former gentleman's paper was "Why Manufacturers Organize," while Mr. Fish discussed the question of the merger of the veneer and plywood associations.

It was also reported that the Quartered Oak Manufacturers' Association had voted to join the National Veneer and Panel Manufacturers' Association as a group. Mr. Potter was also installed as cost engineer of the association.

General view of the C. L. Willey Company's Plant in Chicago, showing frontage on the Chicago River. Our facilities for receiving and shipping, both by rail and water, play an important part in the service we render our customers.

Selected logs are arriving at our plant almost daily, sent in from the markets of the world. Our organization is world wide—our outlet practically unlimited. Willey Veneers are found wherever fine work is appreciated.

C. L. WILLEY COMPANY

The Largest Veneer Plant *in the* World

GIVING you exactly what you want, when you want it, insures satisfaction to you and ultimate profit to us.

That is why we maintain a stock and equipment so large and an organization so wide in its operations that you will always find here just what you want, in any kind of Veneer or Hardwood Lumber, backed by a service that has *your* interests at heart. No other kind of service could have built the largest Veneer Plant in the world—no less in service and supply can keep it going and growing, as it is.

Keep us posted on your needs—immediate or prospective—and we will keep you supplied with samples, of the general character required. You will thus avoid shortages, hurry-up orders, and possible delays.

Will Decorated Furniture Survive?

(Continued from page 76)

containing dry white lead mixed with umber, is dusted over the bright colors then lightly rubbed on the high lights, and the umber and white lead will be retained in the recesses but only partly on the high lights. Many other processes are used. This decoration is mostly adapted to the Italian styles.

Japanese Laquer

So-called Japanese laquer finish is a good enameled, rubbed surface, after which it is striped with gold. Japanese raised designs of trees, bridges and figures are then applied. The designs are first chalked upon this surface. The raising material contains silex, fusil oil, nigrosine and shellac. It is brought to such a consistency that it will barely flow from a small brush and then it is applied to only a portion of the design. It dries quickly and since it contains heating qualities somewhat like lime it melts the enameled surface and securely fastens itself to the wood proper. Therefore, it is non-destructible. Then the artist renders the designed surfaces with generally gold and umber colors, but touches of green, blue, or yellow are also used. The final antiquing is but little known. A coat of laquer containing asphaltum is coated over the striped and decorated surfaces, which having a tobacco brownish cast, gives the gold and other colors a subdued, old effect such as is employed by old English laquer workers. Imitators applying flat bright colors have spoiled this fine art. Only the finer work will endure. Decoration so gaudy that it clashes or detracts from the outlines of the furniture is unlivable and will not survive. Embellishing surfaces with properly designed and colored designs is an art and will not become common.

Group and Individual Electric Drive

The question of which is the most economical and efficient method of transmitting power from the prime mover to the machine is still one which has many reasonable arguments for each system of transmission. It is one which has to be studied from its many sides before an intelligent decision can be made as to what is best suited to the needs of any particular plant.

The three systems in use at the present time are: (1) The long line to which the machines are belted and which in turn is driven by the prime mover; (2) individual motor drive; (3) group electric drive, in which several machines are belted to a short shaft, which in turn is belted to a motor. The long line shaft extending lengthwise through the factory is the time-honoured method of distributing power throughout a woodworking plant. This system is still in use and probably will continue to be used for a good many years.

Individual and group electric drive, however, have come into extensive use in late years and have proved so satisfactory that it has been and is still a common sight to see light-shaft drives being replaced with motor drive, but rare indeed to see a new installation of line shafting in a modern woodworking factory. For the purposes of the ordinary shop or factory, the choice of drive now lies between the individual motor and the group system of driving. Often an engineer can employ both to good advantage, the group system being used for the bulk of the smaller machines, where these are not provided with built-in motors, and individual motors being used on the larger machines, such as those requiring 10 h.p. or more. In planning machine drives one should be governed largely by such considerations as economy of power and maintenance cost, efficiency of the system, depreciation, flexibility as to location of machines, provision for extension and sectional operation, as well as first cost.

Do Not Over Heat Glue

It is important to note that animal or hide glue loses its strength very rapidly at temperatures approaching that of boiling water which are those obtained in the ordinary double glue pot. It is asserted by the Forest Products Laboratories of Canada that hide blues being melted and applied should be maintained at a temperature between 140 and 150° (Fah.) and that above that temperature the strength value of the glue is impaired. In view of the fact it is rather appalling to think of the vast amount of glued work prepared in the past with well boiled glue from which has departed the greater part of its tenacity.

Hardwood Flooring Men Have Outing

A very successful reunion of the sales staff of the Seaman, Kent Co., Limited, Toronto, was held on July 7th and 8th at Meaford, Ont. The party left Toronto early in the afternoon and enjoyed a pleasant motor ride to the northern town. Through the kindness of Mr. Kent and the hospitality of the citizens of Meaford there was not a dull moment in the proceedings The morning of July 8th was spent in a thorough inspection of all departments of the plant and a visit to the yards of the company, and at noon the salesmen were joined by the mayor of Meaford and leading representatives of the town at a dinner at the Paul House, which was thoroughly enjoyed. In the afternoon there was a successful bowling tournament on the excellent green, and during the day a number of the salesmen went fishing.

The return home was made by motor on July 9th, and the outing of the Seaman, Kent Co., who are very busy at the present time in all their hardwood flooring plants, was voted one of the best that has ever taken place in the history of this widely-known organization.

Exhibit of Manufacturers' Lumber Co.

At the recent Made-in-Stratford exhibit, which was held under the auspices of the Chamber of Commerce in Stratford, Ont., a splendid exhibit was made by the Manufacturers' Lumber Co. It comprised wood in its rough state, viz., the log dressed lumber, hoops, staves, etc. A. W. Deacon, secretary-manager of Stratford Chamber of Commerce, says it was one of the most attractive booths at the exhibit and reflected great credit on the enterprise and progressiveness of the Manufacturers' Lumber Co., the members of which are: J. A. McFadgen, C. A. McFadgen and G. A. McFadgen. Besides being manufacturers and wholesalers specializing in various lines of Canadian hardwoods, the company makes staves and hoops of all kinds.

Proper Mill Arrangement and Equipment

(Continued from page 68)

type of machinery, with its large investment, were utilized in producing odd work. Unlike the stock plant rapid production is not vitally essential in the odd work factory, but instead, it is of great importance that machines that can be rapidly changed or set up for small runs be used . By using such lighter machinery in the odd plant, the machinery investment is reduced nearly 50 per cent, thereby enabling the operator to reconcile somewhat the machine burden to the comparatively small output in odd work factory.

When should a machine be considered obsolete? If the inventor should stop inventing and the machine builder stop building better machines than we have today and the user of machines would resolve to keep his present machines in good repair, our present equipment would last almost indefinitely. We do not however, desire the inventor nor the machine builder to discontinue their activities and there is not good reason to believe they will, so it is quite probable that a machine which is perfectly up-to-date today will be obsolete in a short time, either on account of a faster machine being placed on the market or that will do the work with less labor or a cheaper class of help. It is imperative that the individual operator be kept in touch with all new developments, not only that he may successfully compete with his competitor, but that he may assist in contributing towards placing the necessities of life—and especially homes—within the grasp of an increasingly greater portion of our citizenship.

The quality of your sanding affects the finish.

Why Does Clear Oak Flooring Cost Less than Clear Oak Lumber?

Clear oak flooring can be purchased for less than the price of clear oak lumber. Bear in mind that clear oak lumber is being spoken of—a better grade than firsts and seconds. F. A. S. will admit small defects not admissable in clear oak flooring or a clear grade of oak lumber.

What is the explanation of this apparent anomaly? How can an industry subsist that apparently charges less for a completely manufactured article than the raw product from which it is made? An article, too, that requires more men per thousand feet to make than any other article in the dealer's shed.

The fact that oak flooring is accepted in lengths of one foot and up makes possible the manufacture from common oak lumber. It is lengths that give the oak flooring fellow the right to live. And yet how often has the builder contested this reasonable plea for existance by specifying long lengths of oak flooring. The manufacturer does marveously well to give the lengths he does. He must get clear oak flooring out of common lumber and in the cutting necessary to produce it. Long lengths are not possible.

It may be safely predicated that as the years pass, lengths of oak flooring will become shorter than they are today. The supply or large timber is diminishing. A less percentage of uppers is produced and with this a sharper inspection of the lower grades.

When you would examine a planed board as to how it is machined, hold it up sideways to the light, just a trifle below the level of your eyes. You will then readily see all the imperfections.

This photograph was taken of our exhibit at the Indianapolis Industrial Exposition held in Indianapolis last fall, which was attended by more than 150,000 people. Our exhibit was pronounced the finest display of Hardwoods and Veneers at the exposition.

Tapestry as a Furniture Covering

(Continued from page 70)

skill and diligence and also covers a separate branch in the textile industry, the workers being known as twisters. To keep the looms going, ammunition in the form of yarn from the shuttles must be constantly supplied. They are wound on spools or bobbins, usually by girls, on special spooling and winding frames.

In spite of the fact that the personal touch of the weavers is not as emphatic in the present state of manufacturing as it was in the days of old, the individual expression is still being created and is of inestimable value toward further progress of the industry.

The illustrations accompanying this article give an idea of some of the operations involved in the weaving of tapestry, such as is used for upholstering purposes. As stated above, they are reproduced through the courtesy of the La France Textile Co., whose plant is located in one of the great tapestry centres of the world and which boasts of craftsmen to whom fine tapestry weaving is a true art rather than a profession.

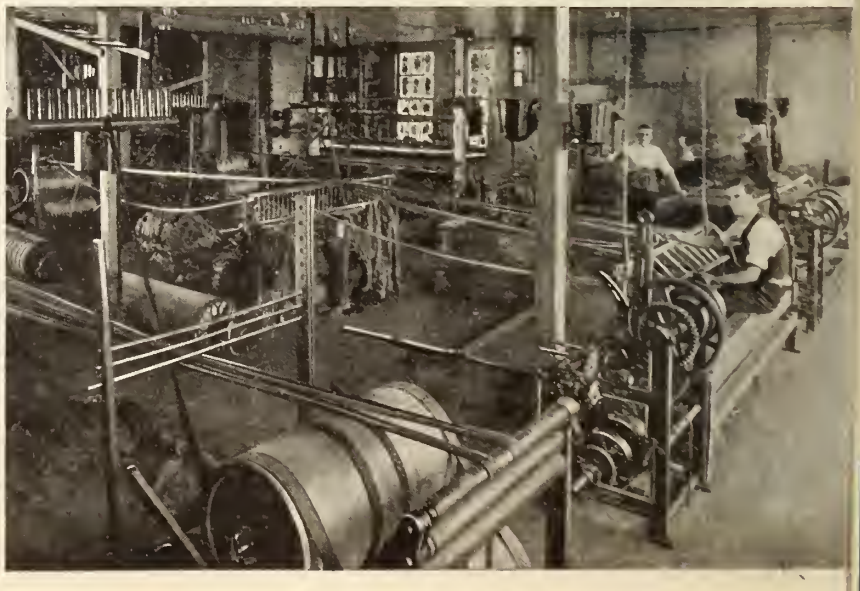
What Is Your Reputation Worth?

S. Karpen & Brothers Find That Integrity and Reputation of Manufacturer Biggest Factor in Selling Upholstered Furniture—Dealer Forced to Rely upon Honesty of Producer

Through a mechanical error a portion of the article in the May "Canadian Woodworker" bearing the above title was omitted from the magazine as printed although included in the proofs. Inasmuch at it offers a timely suggestion to the manufacturer of upholstered furniture the entire article is re-published including the portion previously omitted—Editor]

In no class of furniture does more depend upon honest and thorough factory methods than in the making of upholstered furniture. The integrity of the manufacturer is a big and commanding element.

So much of the quality of upholstered furniture depends upon factors that are not visible to an outward inspection, that this dependence upon the manufacturer looms larger and larger upon deeper considerations. Beneath the covers of upholstered furniture there must be an honest construction all the way through.. Otherwise, no matter what may be



Above: Cloth examining. Right: Long threads of yarns laid out in colors and beamed for weaving

Suggestions of Live Current Items

The usual famous Anderson-Tully service stands behind every foot of the following list of specials which we are pleased to offer the buying trade:

QUARTERED WHITE OAK

4/4 FAS 150,000

Full product of the log in this grade. Stock containing all of the 10" and wider produced, average 7½" for width, 45% to 55% 14' and 16' lengths.

4/4 No. 1 Com. & Selects .....150,000'

Full product of the log in this grade. 45% to 55% 14' and 16' lengths. Stock 8 to 12 months dry.

QUARTERED SYCAMORE

6/4 No. 1 Com. & Bet ..... 75,000'
5/4 No. 1 Com. & Bet. ..... 40,000'

Sycamore is beautifully figured stock, band sawn and equalized, 7 to 8 months dry. 55% to 60% 14' and 16' lengths. All wide in this stock.

6/4 No. 1 Com. & Bet. ..... 100,000'
8/4 No. 1 Com. & Bet. ..... 50,000'

All of this stock thoroughly dry.

Discriminating buyers will find that it pays to be linked with an organization and service so truly founded on an understanding not only of the manufacture of lumber, but of its proper merchandizing and utilization.

ALL STOCK SIX MONTHS AND BETTER DRY

ANDERSON-TULLY COMPANY

MEMPHIS, TENNESSEE

ATCo (MEMPHIS) HARDWOOD LUMBER & VENEER

the attraction of outward appearance, the davenport or chair will not be satisfactory in use and service.

Value Lies in Honest Construction

A trip through the mammoth departments devoted to the manufacture of upholstered furniture at the great factories of S. Karpen & Brothers is a demonstration in the right kind of factory methods that produce that Karpen quality which stands for so much in the furniture industry. Observation of operations in these departments emphasizes the statement that the value of upholstered furniture lies in its honest construction in every part. Expert workers are seen busy at their particular tasks and the constant and exhaustive inspections of every operation makes perfection absolutely sure.

Somehow, there appears to be an especially noticeable degree of craftsmanship and pride in work among the men and women in these departments. It seems that these workers realize the importance of their work and their work gains that indescribable quality that comes only from true appreciation of the importance of good craftsmanship.

One pauses in the department where the frames are constructed, his attention held by the precision with which the work is done. A sturdy, strong and inflexible frame is the foundation of the davenport or chair and without a perfect frame all the embellishments would be lost effort. The frame must be right, there can be no compromise of any kind.

Every Detail Must be Considered

The value of an upholstered davenport or chair lies largely in the way the springs are put in and the manner in which the materials that make it soft and comfortable are placed in position. At first glance one judges an upholstered chair or davenport by its appearance, but the final judgment of its worth comes only after one has sat down in it and measured its comfort. This comfort, and how long the piece will possess this comfort are determined in the departments where the springs are put into place and where the materials used for cushions are fitted into their place.

Of course, right at the bottom of these two essentials lies the choice of the right materials. Good workmanship cannot redeem poor materials in the manufacture of upholstered furniture. The choice of materials in the Karpen factories, as plainly demonstrated by the materials themselves as they are seen in the workrooms and also by the test of service and satisfaction in the use of the finished products, gives the workers full opportunity to win the results of their best efforts.

The quality of the covers of upholstered furniture is another deciding factor. The wealth of the looms of the world finds its way to the cutting rooms and the finished products that are found in the progressive retail establishments of the country and in the homes of America show what has been done in the way of producing beautiful furniture. The use of leather for covers demands special treatment. These skins are prepared by hand work with the same care that the master artisans of the great periods of art production devoted to their chosen tasks.

Careful Inspection Ensures Satisfaction

From the building of the sturdy, strong frame, through the many important operations that carry the chair or davenport to the final touches that makes it ready for inspection, a high standard of craftsmanship rules on every hand. Nothing "just gets by" for every operation must be finally good and right and proper. Each rigid inspection in every department makes sure of that.

The finished article is scrutinized with zealous attention. Nothing can escape the vigilance of such an inspection. The previous inspections send the article along perfect from step to step in the process of manufacture, but the final inspection is really an "inspection of inspections" for before the finished article goes to the packing room, it must stand up in every way under the closest possible inspection.

The trip through the factory is one which strengthens the conviction that the furniture industry is rich in notable institutions that rank high in the commonwealth of production. Furniture helps make the American homes what they are and it is a matter of great gratification to have a tangible demonstration of the integrity of its manufacture in so vivid a manner as a trip through a great factory where true craftsmanship takes the right materials and produces furniture that serves well and adds to the attractions of American home life.—Furniture Index.

Four Billion Foot Saving Through Use of Small Dimension Stock

Continued progress is being made by the Forest Products Laboratory on its survey of the small dimension stock using industries. As the work progresses it becomes more and more evident that much wood material now being used only for fuel or often disposed of as waste is suitable for the small dimension stock of clear quality required by many of the secondary wood using industries. It is also becoming more and more evident that these latter industries can make much greater and profitable use of ready cut small stock than they now do.

The survey by the Forest Products Laboratory has been under way since May, 1921, and the present work is being confined to the chair and wood turning industries. Besides the data being collected by Laboratory crews through intensive studies at chair factories throughout the United States, statistics on requirements on the entire chair industry are also being gathered by other means. Letters were sent out several months ago to all chair manufacturers with the request that they furnish the Laboratory, on forms provided for that purpose, a list of all sizes of small, rough stock required in their chair manufacturing operations. These requests are receiving a hearty response from the chair industry. Through continued co-operation on the part of the chair manufacturers, it is going to be possible for the Laboratory to compile a very complete list of requirements as to size and species of small stock of the entire chair industry.

One of the objections offered by manufacturing plants against the production of small dimension stock, except possibly on special order, has been their inability to locate information on the exact sizes and species of stock required by the various industries. It is for exactly this purpose that the above mentioned data are being compiled. This work is not going to stop with this industry but all wood using industries such as wood turning, furniture, implement and vehicle, automobile, etc., are to be covered in the same

way. When finally completed, information will be available on the requirements of all the secondary wood using industries.

At first glance it may appear that this information will consist of a mass of sizes so complicated and detailed that they will be of no practical use. This will not be the case, however, for from results so far obtained, it has been found there will be a very great overlapping of sizes and species required by the various industries. Thus, a very special size required, for instance by the chair industry in oak or maple may be a standard size used in large quantities by the automobile industry, the case goods producers, or the toy manufacturers. It will be this feature that will simplify the apparent complexity of the requirements of the secondary industries and hence will put the entire scheme on a practicable and usable basis, not only for the consumer of small dimension stock but also for the manufacture of such stock. Incidentally, the commercial application of the results of this product should save annually 4 to 5 billion feet of our diminishing timber resources.

Standardization of Lumber Grades

Grade Rules, as They Exist, Are Not the Result of Scientific Study, nor is There Any Scientific Adaptation of Grades to Consumption Needs — Official and Unprejudiced Inspection Is Needed

By Landon C. Bell*

U. S. Secretary of Commerce, Hoover, in giving the lumber industry the vision of a standardization of nomenclature, grades, and guarantees, and of the benefits to accrue from an agency for the administration, nationally and internationally, of an inspection service embracing all woods, has rendered it a service of inestimable value.

The accomplishment of a system of standard names, standard rules for the grading and inspection of lumber, and the adoption of effective means, such as grade-marking the lumber, car cards, showing quantity and quality of the lumber, and other means for assuring the integrity of grades and quantity, and to prevent grade manipulation, would mark an epoch in the industry. If in addition, an independent, impartial agency, national in scope, undertook to supply everyone who desired it an inspection service at a reasonable cost, the industry would be approaching a plane of great improvement, and undoubtedly would command the public confidence in a way that has been lacking in the past.

Especially noticeable would be the improvement in respect to the hardwood industry, where because of the great variety of woods and consequently the multiplicity of grades, clarification and standardization is greatly needed; furthermore the internal dissensions regarding the control of inspection service has been such as to create doubt in the public mind as to the adequacy and integrity of the instrumentalities heretofore controlling the service. Certainly the refusal of the service, except to members of the association supplying it, has been wrong and is indefensible.

Grade rules as they exist at the time Mr. Hoover makes his suggestions are certainly not, at least in the hardwood industry, conducive to the most perfect utilization of the lumber. The best informed thought, practical and technical, is practically unanimous in the view that the rules are of more or less haphazard growth, and are not the result either of scientific study or scientific formulation. They are not such as to scientifically conform production to consumption requirements.

It is the effort of the standardization movement to make the necessary analysis of the production possibilities from the woods, likewise the necessary analysis of the consumption requirements of the products, and thereupon to scientifically formulate and define the rules in such way as to allocate the available supply to the consuming industries in proportion to their needs and demands so that the products of the manufacturers may be utilized with the least waste and therefore at the lowest cost to the ultimate consumer.

The lack of scientific adaptation of grades to consumption needs often results in the consumers being burdened with a large amount of by-product or so-called waste material, for which he really has no use, but for which he must find one, or else the material becomes a total loss in his hands. Capable authorities estimate that the amount of such waste can, by the perfection of the standardizations proposed, be reduced many per cent—estimates ranging variously from 60 to 70 per cent.

The universal approval among consumers of the proposals of the Secretary of Commerce is indicated by the following paragraph from a publication serving the wood-working industry, in which it was said:

"The woes of the wood-worker have been largely due to a plethora of patterns, defective nomenclature, confusion in grades, etc. With his usual foresight and energy, Secretary Hoover has singled out this weak spot in the trade and begun remedial measures. The four-day preliminary conference of American lumbermen which he called reflects a unanimous opinion which will undoubtedly result in much standardization, in definite nomenclature, universal grades, markings and practices. It looks as though a national system of inspection and certification would be established, to embrace the entire lumber trade, that descriptions of different species of lumber will be made as uniform as possible, that inspection service will be open to consumers in settlement of all disputes, and that this system will be extended to foreign consumers. It will certainly be a great satisfaction to the consuming trade when all sources of supply are governed by uniform rules and standardized grades protected by official and unprejudiced inspection.

Such a scientific adaptation of production to consumption requirements and a fuller understanding by consumption of the possibilities of supplying its needs will tend to a more perfect utilization of forest products, and not the least important of the consequences will be the resulting conservation of our timber resources.

*Chairman, Press and Publicity Committee, Hardwood Manufacturers' Institute.

Uniform Lumber Means Greatest Satisfaction To The User!

You no doubt have experienced the expense, loss of time, and loss of materials, caused by the use of improperly cured, wrongly graded, and carelessly handled hardwood.

Kraetzer-Cured Lumber is absolutely uniform in quality, properly graded, and every board plainly marked, showing the grade. To show our faith in Kraetzer-Cured products, every board is stamped with our brand.

THE KRAETZER-CURED LUMBER CO.

Because of our unusual facilities we control the lumber from the virgin growth to the time it is loaded on the cars and shipped to you.

When you have once used Kraetzer-Cured Lumber you will not be satisfied with the ordinary kind. Read the eight important reasons why Kraetzer-Cured Gum is used by thousands with such satisfactory results. It will give the same results to you.

Kraetzer-Cured Lumber is of the very best quality, carefully handled by all departments. Every step in this process is taken with the idea of producing uniform high grade hardwood that w ill give maximum service in your hands.

In addition to Kraetzer-Cured Gum, we can furnish Oak, Ash and other Southern Hardwoods.

The Kraetzer-Cured Lumber Co.

GENERAL OFFICE: GREENWOOD, MISS.

Band Mills: Greenwood, Miss., Moorehead, Miss. Leflore, Miss.

You Should Use KRAETZER-CURED GUMWOOD *Because:-*

1. It is STRAIGHT and FLAT, free from the warp and twist usually encountered in untreated stock.
2. It is BRIGHT and will satisfactorily take any finish.
3. It is free from dote or rot—the sap and gums are eliminated by the steaming process. and fermentation and decomposition are thus prevented.
4. Through the elimination of stain and decomposition, it possesses greater strength and longer life.
5. It contains only atmospheric moisture, enabling it to be used for many purposes without kiln drying.
6. When kiln drying is necessary, this can be done in much less time and with more satisfactory results.
7. It is uniform and dependable. One car like another, grade and measurement what it should be—no time w a s t e d in reporting complaints or shortages, no delays or interference with factory schedules because of holding lumber for adjustments.
8. It is the most economical lumber available. It will satisfactorily answer any requirements expected of materially higher priced woods. Join our little army of satisfied users, and just as peace is about to supplant war, let peace of mind take the place of the warfare and worries that usually beset the user of lumber.

We're proud of this product —that's why.

News of the Trade

E. B. Eddy Co. Limited, Hull, Que., are preparing plans for an addition to their match factory to cost about $1,000,000.

Dominion Hammock Mfg. Co., Limited Dunnville, Ont., are building a new factory building at a cost of $50,000

The Board of Education of Renfrew, Ont., is receiving tenders for the construction of a new collegiate at a cost of $200,000. No seating equipment has yet been purchased.

Work is expected to start shortly on the interior trimmings of the new church at St. Maxime De Scott, Que. Rev. E. Bernard is the priest of the parish.

Donald F. Johnston Radio, Ltd., Toronto, were recently incorporated to manufacture all kinds of radio cabinets and other wireless apparatus.

The consolidated School, Queenston Rd., St. Catharines, Ont., is receiving tenders for alterations and additions to the present building. J. Newhouse is one of the trustees.

Walter G. Woolley, 231 Indian Grove, Toronto, a cabinet finisher with the Brunswick Phonograph Company, recently passed away in his 41st year.

Spruce Falls Investments, Ltd., Kapuskasing, Ont., have been granted a provincial charter to operate planing mills and manufacture and deal in wood products. Capital $40,000.

Wm. Rutherford & Sons, Limited Ottawa, Ont., recently secured the millwork contract for the new Fairmount Presbyterian Church, at Montreal.

Doon Twines, Kitchener, Ont., manufacturers of factory twine, are calling for tenders for the erection of an addition to their factory to cost about $35,000.

IXL Manufacturing Co., Palmerston, Ont., battery makers, recently suffered a fire loss of $15,000. The company contemplate rebuilding in the near future.

Radiola Company, of Canada, Limited, Ottawa, Ont., were recently granted a federal charter with a capital of $100,000 to manufacture and deal in radio equipment.

W. F. Vilas Co. Ltd., Cowansville, Que., manufacturers of school and office furniture, report business as good with them, factory running day and night.

Sturgis Baby Carriage Co., Sumach St., Toronto, are contemplating building a two-storey brick factory at Brampton, Ont.

The Canadian Match Co., Pembroke, Ont., are asking for tenders for a new match factory which they contemplate building.

Broomsgrove Guild of Canada, Limited, Montreal, was awarded the contract for the fixtures and interior woodwork for the new cafeteria being erected by Cordner's Limited. Montreal.

The Dowse Sash & Door Co., Limited, St. Boniface, Man., have been given the contract for the woodwork in the new film exchange being erected at Winnipeg at a cost of $170,000.

Quebec Hardwoods, Limited, Montreal, were recently granted a provincial charter to manufacture and market all kinds of forest products. Capital $50,000.

J. Walter & Sons, Kitchener, Ont., manufacturers of wood fibre products, are calling for tenders for a new factory building. The estimated cost is in the neighborhood of $25,000.

The School Board at Hickson, Ont., are building a new school to cost $12,000. Foundations are in and seating equipment will soon be required.

Lyons Bros., Plymouth Ave., Toronto, manufacturers of wood boxes for storage batteries, have installed equipment for making wood separators for batteries.

Robert Stewart, Limited, Guelph, Ont., manufacturers of sash, doors and all kinds of interior trim, are contemplating the erection of a dry kiln as a supplement to their new factory building.

Mr. R. Smith has opened an upholstering, furniture repairing and polishing, and cabinet work business at 29 King St., St. Catharines, Ont., under the name of the Niagara Cabinet Works. He reports business very good.

A new school is being erected in Winnipeg, by the school board, which will cost $79,988. The millwork is being supplied by A. R. McDiarmid Co. Ltd., Brandon. Seating equipment has not yet been purchased.

Frederick Martin, 356 Sumach St., Toronto, for many years connected with the piano manufacturing business, died recently in his 80th year. Deceased was employed at different periods with Jacques & Hay, Nordheimer Company, Heintzman & Co. and Gerard Heintzman.

Messrs Sangster Bros., have opened a sash and door factory at Niagara Falls, Ont., equipped with modern machinery, and although operations were commenced but recently, they report business as very good. The members of the firm have had many years experience in carpentry and joinery in the Old Country.

Made-in-Stratford exhibit at the Canadian National Exhibition have secured 10,000 square feet in area in the West corner of the Coliseum. Among those in the Stratford delegation who visited Toronto to select the location were Messrs. S. J. Cook, F. W. Trebell, H. W. Strudley, F. M. Gifford and Duncan Ferguson.

Arthur Gore, of St. Thomas, Ont., recently invented an apparatus for drying dishes and has applied for patents. The contrivance is made entirely of wood and at present is being hand-made. Mr. Gore is carrying on his little business in a wood shed at the rear of his home and if the drying device is a success the business will be removed to larger quarters where woodworking machines will be employed.

The Hanbury Co., are installing machinery from Sawmill Machinery Co., Hackettstown, N. J., which was purchased through the General Supply Co., of Canada, Winnipeg. The firm will cut their own timber from the Riding Mountains. The Hanbury Co. who manufacture boxes of all kinds, crates, shooks, cross-arms and open sash, have one of the largest plants west of Ontario.

One of the many new pieces of equipment installed in the new woodworking plant of Robert Stewart, Limited, Guelph, Ont., is a machine made by H. B. Smith, of Smithville, N. J., for cutting the zig zag grooves in stair stringers, into which the risers fit. The machine may be used on any kind of wood and is a great help in the manufacture of stairs.

Standard Lumber & Supplies Limited, who were recently granted a charter, are opening a lumber yard at the corner of Giles & Mercer Sts., Windsor, Ont. E. J. Kerby is the secretary and treasurer of the compony. E. Allen, who was for a number of years with Robert Stewart, Limited, of Guelph, is a member of the organization. It is probable that the Standard Lumber & Supplies will later on put up a plant of modern size and carry a full stock of building materials.

Plans are drawn for the new Central Church of Christ, Patron Rd. and St. Clarens Ave., Toronto. An organ will be purchased and also seating equipment.

Durant Motors of Canada, Ltd., Toronto, are asking for tenders for an addition to their automobile factory at Leaside, Ont., to cost $500,000.

H. H. Clark, of Coaticook, Que., is building a new mill and equipping same with new up-to-date machinery for the manufacture of handles, dowels and turned goods. Water power for running the plant will be supplied by a stream running through the property, connections having been completed recently.

George Robinson, an employee of the Rodney Woodenware Company, while oiling a machine in motion, was cut to pieces when his clothing caught in the wheels. He was sixty years of age and was a former resident of West Lorne, Ont.

A. E. Stanners, who has been for the past twelve years associated with the Seaman, Kent Co., Toronto has been appointed sales manager, succeeding W. T. Cole who recently resigned to enter business for himself. Mr. Stanners was for some time the representative of the firm in Winnipeg, and later in Montreal, and during the past few years has looked after part of Toronto and Ontario. He has entered upon his new duties.

Foundations for a new school which will cost about $60,000 are going in at Edmundston, N. B. The school board has not yet purchased any seating equipment.

The Dominion Fabrics, Limited, Dunnville, Ont., have been granted a provincial charter to manufacture and sell furniture coverings over drapes and other textile goods and fabrics. Capital $250 000.

G. W. Wyckoff, president of A. Wyckoff & Sons Co., Elmira, N. Y., manufacturers of wood water pipe, died recently in Washington, D. C., following an operation. He had many friends in the lumber industry in Canada with whom he had, in years gone by, extensive business relations. Frank H. Horning of Toronto, who was for a number of years associated with the firm, attended the funeral of Mr. Wyckoff.

Jewett Radio-Phonograph, Limited, Windsor, Ont., have leased a factory in Walkerville, Ont., where they will manufacture their combination phonograph and radio machine. E. H. Jewett, one of the heads of the Paige Detroit Motor Car Co., and president of Jewett, Bigelow & Brooks Coal Company, is the leader of the Canadian concern.

Word received from Huntsville, Ont., is to the effect that the Muskoka Wood Mfg. Co., whose flooring plant and sawmill were destroyed by fire a few weeks ago, have purchased a sawmill in Algoma and are having it moved to Huntsville. Some of the equipment has already arrived and workmen are preparing the foundation for construction. The new mill will have cutting capacity of some 40,000 feet a day, and will be in operation about the middle of August. Regarding the re-ercetion of the new flooring factory, no decision has been arrived at, at the present time.

The Industrial Specialty Mfg. Co., of Magog, Que., have lately purchased the sawmill and equipment of O. Langlois whose plant adjoined their own. The Industrial Company are cutting this season about 2,000,000 feet, three-quarters of which is hardwood and the remainder softwood. The company report that their woodworking plant being very busy at present. Spindles, spools, bobbins, shuttles, specialty lines, and hardwood flooring are turned out by the firm, who also do a large wholesale lumber business.

The Separate School Board of Arnprior, Ont., are finishing the interior of their new school. 160 seats are to be purchased. G. O. Devine, Box 132, is secretary.

Gold Medal Radio-Phonograph Corporation, Limited, Uxbridge, Ont., have been incorporated with a capital of $300,000 to manufacture and deal in phonograph and radio cabinets, furniture and other wooden products.

Aquamobile, Limited, Toronto, have been granted a provincial charter to manufacture and market all kinds of wooden boats. Capital $40.000.

Messrs. Fred Holmes & Sons, Toronto, have the contract for installing organ and decorating Shea's Hippodrome, on Terauley St., Toronto.

A new corporation, known as the Beaver Products, has been formed to acquire the Beaver Board Company. They will operate 17 manufacturing plants in Canada. At the present time, the Beaver Products Corporation has issued $3,000,000 first mortgage and refunding, 20-year, 7½ per cent. sinking fund gold bonds.

C. J. Chaplin, supervisor of timber tests at the Forest Products Laboratory, of Canada, McGill University, Montreal, recently announced that after numerous tests, Canadian poplar has been discovered to be suitable for cigar boxes. The imported havana cigars are sold in boxes made of Cuban Cedrela wood. Canadian tobacco manufacturers will be glad to learn that poplar can be treated to resemble the Cuban wood which seems to have gained as much reputation as the different brands of cigars themselves.

W. H. Cushing, of Cushing Bros., sash and door manufacturers, Calgary, states: Building operations in the prairie cities have created an increased demand in the past few months for B. C. lumber. Mr. Cushing, who was Minister of Public Works in the Rutherford government, is president of Cushing Bros. Ltd. "Optimistic views are held about the crop and if they materialize," he said, "the farmers will also enter the market and create a really good demand for B. C. lumber. It is several years since they bought in any quantity and there is a lot of work to be done when the farmers get the money to do it. The West has been having good rains, but a lot more is needed as the ground is dry, but on the whole the outlook is considered good."

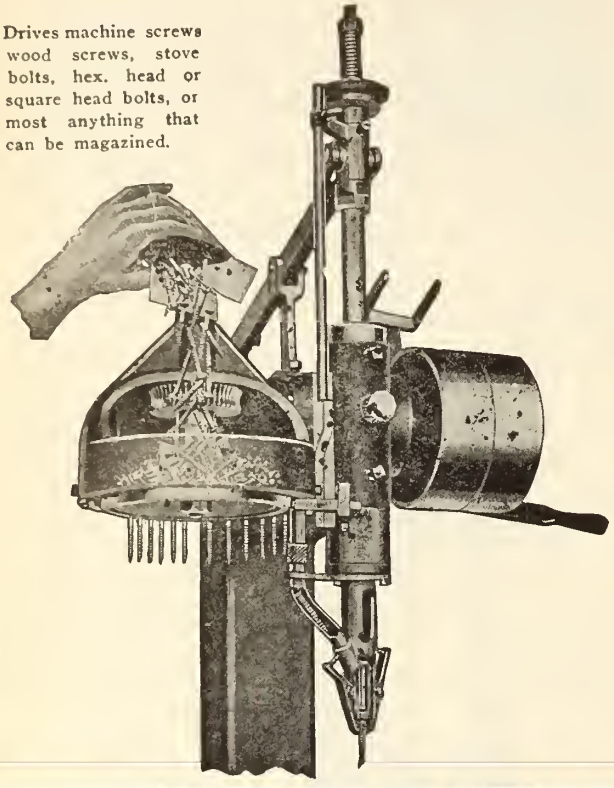
RICHARDS-WILCOX CANADIAN CO., LTD., LONDON, ONT.

The Demand is for Lower Prices!

Drives machine screws wood screws, stove bolts, hex. head or square head bolts, or most anything that can be magazined.



Reynolds Automatic Screw Driving Machinery will help you meet the demand

Everywhere the manufacturer is faced with the problem of price reduction. How can he find the solution?

By cutting out every waste—of time, labor materials, etc.

Many manufacturers have installed Reynolds Screw Driving Machinery for this reason. It accomplishes the work-better in one-third of the time.

Consequently they are able to meet the demand for lower prices and hasten the return to normal buying.

Are you interested? Then write us to-day for the full facts.

Send us dimensions over all of your work and gauge and length of screws driven so that we can determine the proper size and type machine to meet your requirements.

A Small Article
of Great Importance

Realizing the importance of efficient casters, we have made a specialty of this line and as proof of their quality we need only say that many of the foremost furniture manufacturers are using them exclusively.

By the way don't it seem logical that a Canadian-made caster should be the right one to use on Canadian-made furniture? Assuming of course, that it equals the standard of the imported article?

If you believe so too, just write us for samples and prices.

Some Wood Sinks

Wood floats. That is a fact so familiar as to need no comment. Nevertheless, there are certain woods so dense of structure and therefore so heavy, as to sink in water.

One of them is the "mancono" wood of the Philippines—unknown to us until recently, but which, it is hoped, will serve as a substitute for the costly lignum vitae.

Lignum vitae is the wood of a tree native to the American tropics. Some of the best of it comes from Cuba. Its name, meaning "wood of life," was bestowed upon it by the early Spaniards, among whom a belief arose that it possessed almost miraculous properties as a cure for various diseases.

The best bowling balls are made of lignum vitae; also heads for golf clubs and other things requiring an extremely hard and heavy wood. But the most important use of this material is for the steering gear of ships. The propeller shafts of every warship and commercial steamship revolve in bearings of lignum vitae.

The great strength of this remarkable wood is due to the fact that its fibres are woven back and forth in layers that cross and crisscross. Its cells are filled with resin, which acts as a lubricant and enables it to resist saturation by water. Propeller bearings made of it are almost wearproof.

Lignum vitae weighs 80 pounds to the cubic foot and is therefore, much heavier than water. It will not float. Good logs sell at 52 cents a pound.

Another nonfloating wood is "quebracho," which is only less heavy than lignum vitae. It comes from a tree that grows over vast areas, scattered through the forests in Brazil and other parts of South America.

This wood is so hard that highly tempered tools are needed to work it even when it is young and green. It will soon blunt the keenest axe. Nine railway ties made of it will weigh a ton. It is fine-grained and takes a beautiful polish, the sapwood being nearly white and the heartwood cherry red. In South America it is much used for furniture and interior finish.

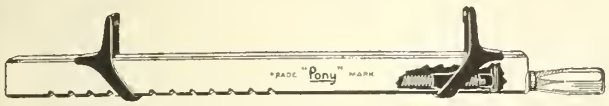
But the greatest value of quebracho lies in the extract obtained from it for tanning high-grade leathers—Service.

With the continued healthy activity in construction throughout the Dominion many lumber wholesalers are finding themselves seriously short of material to supply the demand. Such a situation is not a surprise according to reports from the different producing centres, particularly in the east and many manufacturers who have not been operating for the last two years are now witnessing a demand for construction material that is paying them to again start up their mills.

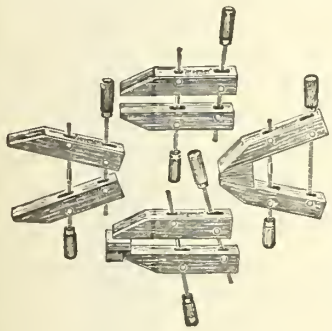
Hardwood flooring and interior trim producers have been very active since early spring. The automobile manufacturers are the chief consumers of hardwoods at present, especially thick elm, ash and maple. Wagons and carriage makers are witnessing a lull and musical instrument and agricultural implement makers are practically buying no supplies. The furniture factories are generally marking time and no large quantities of material are moving that way during the warm weather. However, everything points to a fairly prosperous year with the farmers both east and west and together with the completion of the building programme the demand for house furnishings should be healthy this fall.

It is only natural that the much looked for demand of wood materials of all kinds would present itself in the softwood market first, and if homes and industrial buildings continue to be built at the present pace for the remainder of the year the demand for better grades of both soft and hard woods is certain.

"Pony" Cabinet Clamp



For lightness combined with strength this clamp has no equal. All parts are selected from the best materials obtainable and we have spared no effort to make the "Pony" the finest thing of its kind on the market. Made in sizes to open 18 in. to 72 in.



"Jorgensen"

Peerless Adjustable Hand Clamp

Fits every grip without a slip and takes a tighter hold with less effort. It is a tool of real economy and a clamp that insures efficiency.

Installation at the Housing Corporation, Waltham, Mass.

A Vacuum Cleaner at Every Cutting Head

That is exactly what a correctly designed collecting and conveying system means in your plant.

But the system must be installed so that the mill may be kept entirely free from refuse and waste, even when you are running at maximum speed and capacity. There are many other problems connected with your output which must also be taken into consideration.

And that is where the long, varied experience of our collecting and conveying specialists can be of inestimable value to you.

Our engineers will be glad to look over your plant—without the slightest obligation.

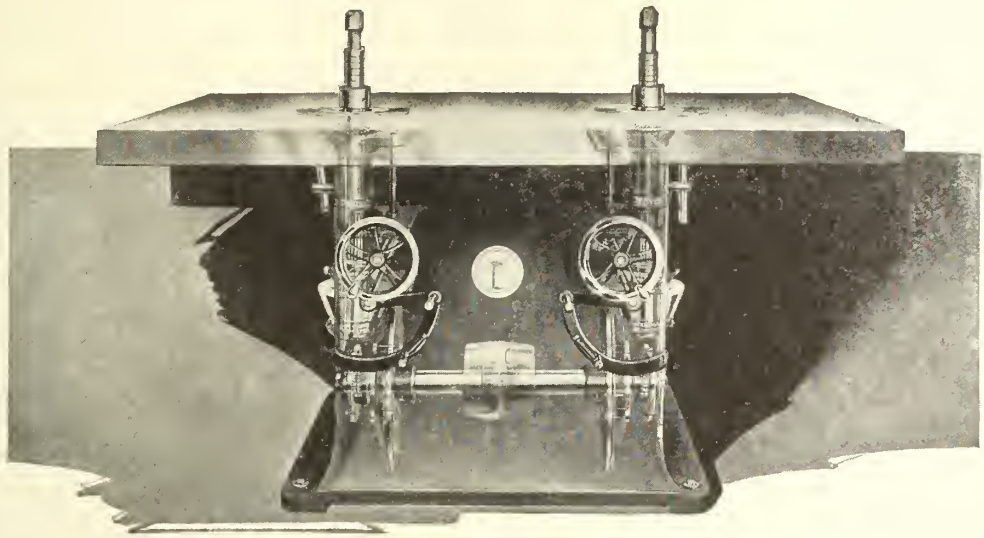
SKF



Ball Bearings Permit and Maintain
High-Spindle Speed with Accuracy and Low Power Consumption

SHAPER operators know that if there is friction in the shaper bearings sufficient to cause wear and misalignment, the consequent vibration soon becomes a potent force of destruction which rapidly ruins the serviceability of the shaper. When self-aligning ball bearings are used the inner race tilts with the shaft and the bearing can never bind.

Spindles thus equipped require less power, run smoothly and silently, and remain absolutely true. As a result, the worker can do his work more easily and obtain a greater output. At the same time his machine is not subject to frequent shutdowns. Ball bearings eliminate the wearing, rubbing friction which causes burnt-out bearings and an endless round of troubles that lower production and eat up profits.

See that all your shapers are equipped with **SKF** marked ball bearings. They effect remarkable savings in power, belts, time and labor, and enable the tools to maintain high speed with lower power consumption.

Three Operators With But a Single Thought—

The Efficiency Of Carborundum Brand Garnet Products

HERE are three men doing three widely varied sanding jobs and doing them mighty well.

One is sanding gumwood boxes for toy blocks. He takes 1/64 off the four sides sanding 1,000 boxes complete with one Carborundum Brand Garnet Belt.

He says he never had a belt to do the work so well.

Another is sanding washing machine bottoms on a drum sander. His comment was that "Carborundum Brand Garnet stands up better—does more work, lasts longer. We have no kick of any kind."

And then we have the hand sanding of phonograph cabinets. The operator here says that he gets a cleaner, more uniform finish, the paper doesn't crack or peel and it's fast cutting and extremely flexible.

Carborundum Brand Garnet Products
Make Good Sanders Better Sanders

The Carborundum Company

Save Money in Your Boiler Room

Any power plant up to 500 h.p. can make important fuel savings with the National Hand Fired Stoker. Not only that but ordinary labor can give you expert fireman stoking results through the simple manipulation of the Push Rods that keep the fuel moving downward on the fire bed.

Perfect combustion, with any type of fuel, and no smoke are outstanding results.

Made by us in Canada. Can be installed in your present plant. Let us send you illustrated descriptive booklet.

Morgan No. 6 Nailing Machine

MORGAN
NAILING MACHINES
Used in Nailing Wooden Toys

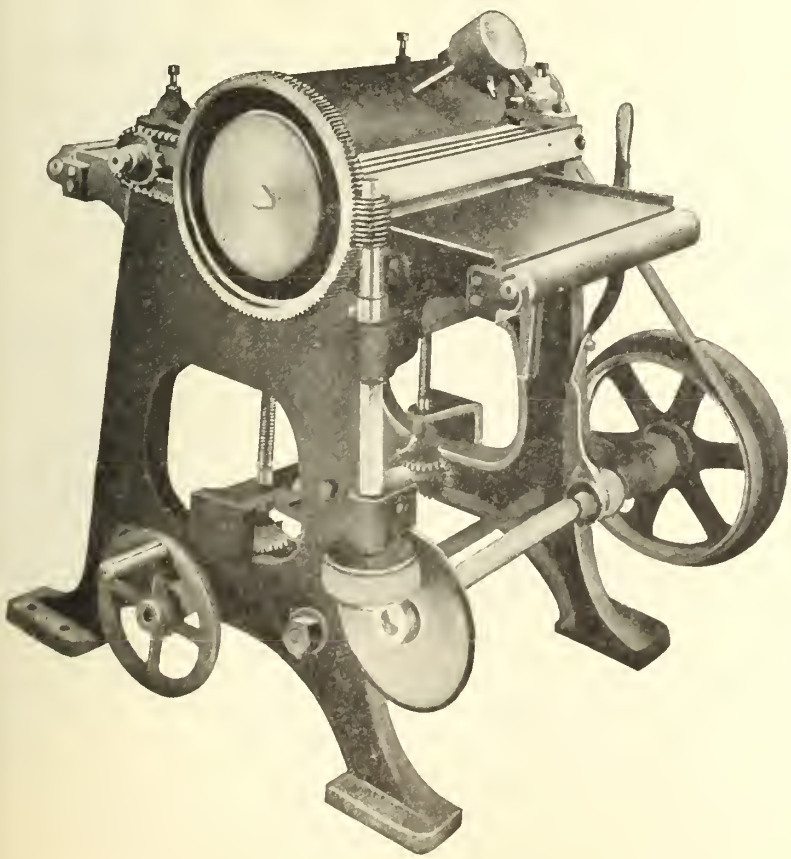
Many manufacturers of American Wooden Toys use our machines for driving 5/8" to 1 1/8" nails. Machines are adjustable in operation and can be adapted to any kind of nailing work.

If you are driving nails by hand in making boxes, crates, toys, any woodenware articles, figure the cost. It is expensive.

Then send us samples of your work. Get an estimate of the cost of nailing on a Morgan Nailing Machine. Compare the figures. We'll leave the rest to your judgment.

Send us your nailing problems. We shall be pleased to give them our careful consideration and advise you regarding equipment for handling them. We invite your inquiry.

Morgan Machine Company
Rochester, N. Y.



The Elliot Bull Dog Planer

6" x 16"

The facts that the head is run by a worm gear; no pinions on the head and that the feed rolls are driven independent of the head excludes vibration. Hence—it planes smoother than any other Pony Planer made. Also it uses less power.

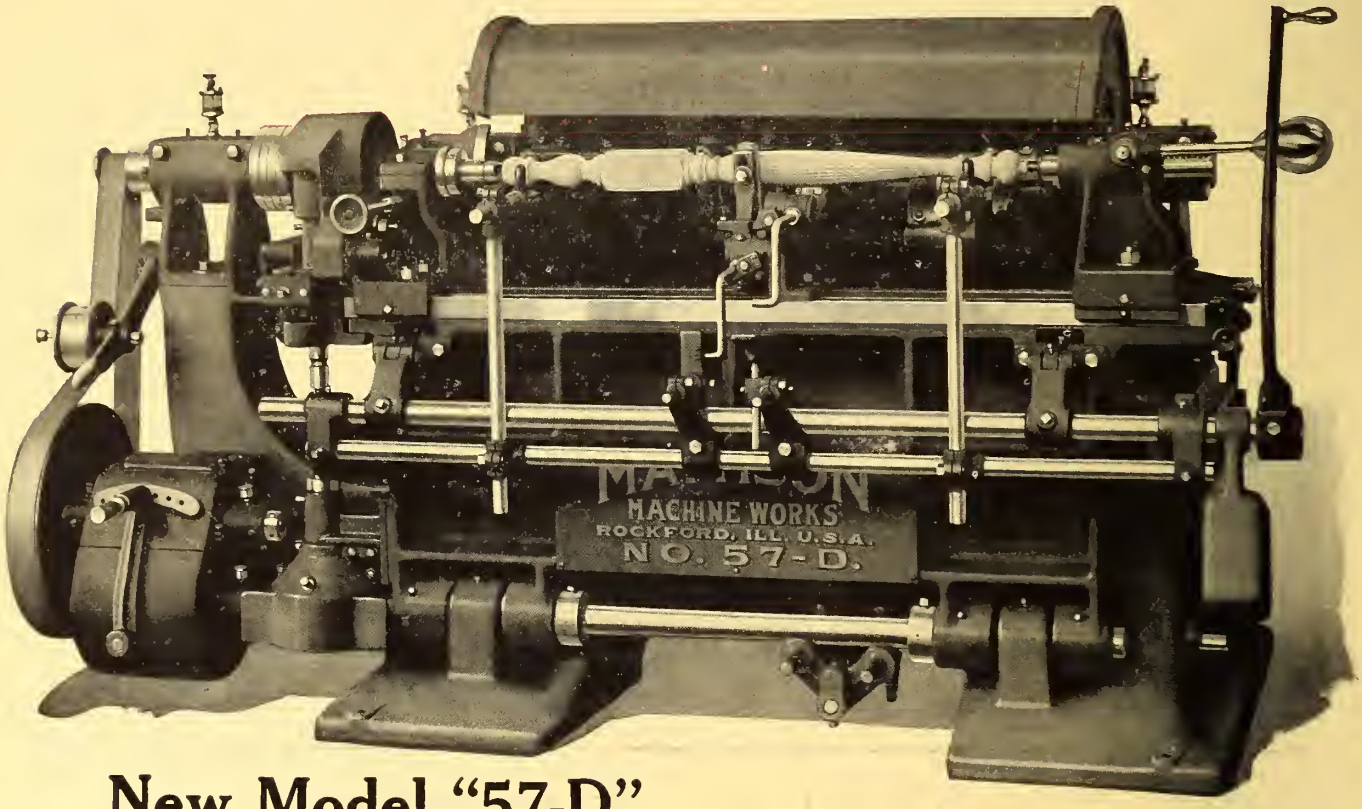
The Latest Improved Mattison Lathe

The Standard Machine Turner



New Model "57-D"

IN this New Model D Mattison Automatic Shaping Lathe are found the many improvements and refinements which twenty-five years' experience have shown to be desirable and necessary in a machine of this type.

It is not a radical departure in principle, nor is it a case of taking an old machine and patching on a new piece here, or cutting out something there. Yet it has been completely redesigned from the ground up. It has been made heavier where added weight is essential. Its operation has been made more convenient and faster. Attachments have been simplified to facilitate adjustments and to save time when changing. Gearing has been changed to eliminate readjusting when substituting different work-holding devices, thus insuring the gears against undue wear.

In a word, the developments and refinements on this new Model D Mattison Automatic Shaping Lathe leave nothing to be desired as to efficiency, operating convenience and simplicity. It is the culmination of twenty-five years' experience in continuously developing a principle proven right at the start.

The Specialty House on Woodworking Machinery

Described below you will find a collection of **Moulders** and **Saws** taken from our present stock of **New, Rebuilt** and **Used Machinery.** We are in a position to quote very attractive prices on these machines for the reason that every machine on our floor has been recently **Repriced** to **New Low Figures.**

NEW with us means machine has never been in operation
REBUILT means re-manufactured by us in our own shops
USED means machine is in good working order

Write now giving the number of machine you are interested in and we will promptly place before you full particulars and prices.

Stock No. MOULDERS.

2628 Cowan 13" Four Sided Moulder, square heads on top, bottom and side spindles, top head fitted with slats close to lip for use of beading and other small cutters; solid type top and bottom heads; straight knives on all heads; similar to Cowan M-152; side heads 5" high, tight and loose pulleys.

2621 Hespeler (similar to C.M.C. 303) 10" Four Sided Moulder, square heads on top, bottom and side spindles; top head slip on type; side heads 4" high, straight knives on all heads; tight and loose pulleys.

2629 American (Houston) 8" Four Sided Moulder, square heads on top, bottom and side spindles; solid top and bottom head, side heads 4" high; straight knives on all heads, tight and loose pulleys.

2635 Cowan 10" Four Sided Moulder, square heads on top, bottom and side spindles; top head slip on type; side heads 4" high, straight knives on all heads; similar to Cowan M-223, tight and loose pulleys.

2636 Cant-Laidlaw 8" Four Sided Moulder, brass heads fitted to all spindles, top head 9" long; bottom head 8" long, side heads 4" high; rear table swings to back of machine; straight knives on all heads, tight and loose pulleys.

2637 Cant-Gourlay 8" Four Sided Moulder, brass heads on all spindles, side heads 4" high; rear table swings to rear; straight knives on top, bottom and side spindles, tight and loose pulleys, old type open frame machine.

2638 Two Sided Dowel Sticker, top and bottom spindles; for running flag sticks, equipped with heads knives for ⅜" rounds; heads 5½" long; cutters 3⅝" long, two cutters to each head; two infeed rolls 4" dia. table lowers for stock approximately 3" in thickness; has countershaft with tight and loose pulleys, similar to McGregor-Gourlay XP or Cowan M-149.

2634 Cowan 12" Four Sided Moulder, square heads on top, bottom and side spindles; solid type top and bottom heads, side heads 4" high, straight knives on all heads, similar to Cowan M-152, tight and loose pulleys, ball bearing loose pulley.

SAWS.

2593 American Fig. 6385 No. 30 Double Arbor Universal Saw Bench, table in two sections which separate for use of dado heads or other heads up to 2½" wide; stationary table 23" wide; movable or sliding table (which moves on six rollers as well as on slide) 17" wide; table 40" wide x 48" long, capacity rips from 1/16" to 27½" and cuts off to 31" wide when saw is set for 2" stock; whole table tilts to any angle up to 45 degrees, carries saws up to 18" diameter, equipped with one 18" rip saw, one 18" crosscut saw; micrometer rip gauge; three sliding cut-off gauges, swivel type; movable table laid out with bevel protractor or 180 degree circle with pin holes for all principal angles for cutting off on angle; countershaft with tight and loose pulleys (new machine).

2599 American Fig. 5610 No. 25 Edging Saw, fitted with saw in table, with two movable chains running one on either side of saw, with fill-up plate in front of and in rear of saw blade, preventing splinters from getting under chains; four adjustable top feed rolls; capacity stock as short as 5" up to 20" wide; using a 14" saw stock 3½" can be ripped; saws up to 16" can be used; table is 52" long and 32½" wide, speed of feeds, 48', 86' and 140' lineal per minute, equipped with one 12" saw blade; arbor outside of frame, no countershaft; (new machine).

2602 American Fig. 5859 No. 3 Double Cut-off Saw, with self-contained countershaft, equipped with friction power feed to movable headstock in addition to ordinary hand wheel movement; bevel rip gauge, sliding cut-off gauge operates on accurately planed ways and rolls; for square cutting off; capacity is from 8" to 6' 9" in length, 4" thick and 30" wide, two 16" saws 1¼" hole included; tight and loose pulleys on countershaft (new machine).

2610 American Fig. 575 No. 2 Hand Feed Rip Saw, with arbor pulley outside of frame, no countershaft, extended arbor for saws 10" between inside and outside saws, table hinged at rear and raises by hand wheel; adjustable rip gauge; capacity rips up to 24" wide and stock up to 4" thick; table is 38" x 54", arbor pulley 7" x 7¼" runs 2400 r.p.m. one 16" saw 1¼" hole included.

2612 Blind Slat Resaw, similar to McGregor-Gourlay T.N. suitable for blind slats or other similar stock, carries gang of saws on arbor with series of collars; length of arbor 7", on countershaft, diameter of saw blades 6".

2622 Preston No. 132 36" Band Saw, with solid lower wheel, one ½" saw blades, tilting table, self-contained tight and loose pulleys.

2631 Mershon Band Edging Saw, 14" wheels, 3½" blade, infeed table, with friction adjustment to rip gauge, top feed rolls, with return roll for stock, self contained countershaft.

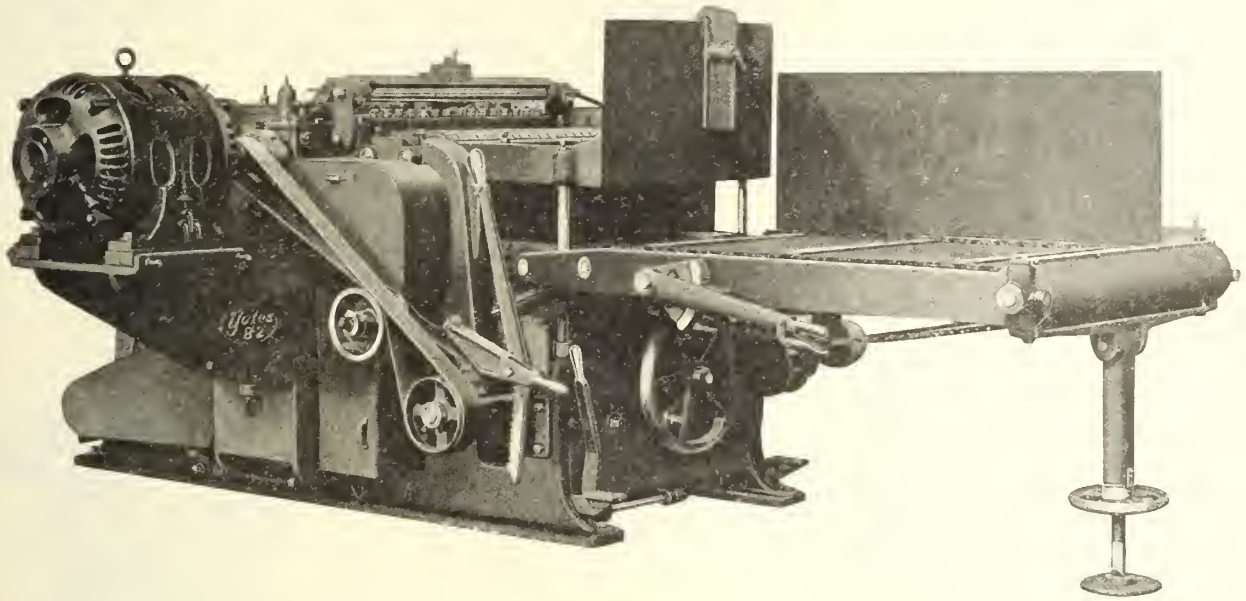
Hamilton, Ontario

The Newest Thing in Surfacers— The Last Word in Efficiency



Yates

TYPE B-2 DOUBLE SURFACER

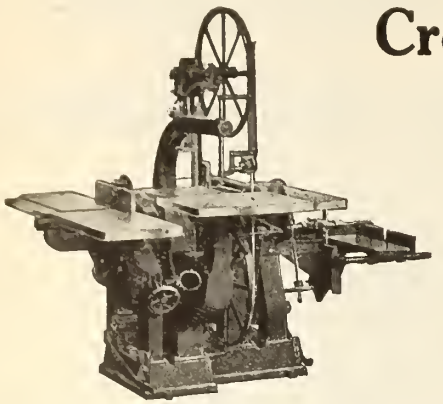
Yates

Built for Furniture, Box Factories and the average Planing Mill. Nicknamed the Price of Production, because it produces the goods in a Princely manner. Gives a high grade finish at speeds up to 100 feet per minute. With Hopper Feed as shown, short stock can be piled on the hopper and surfaced as fast as long stock. Durable – compact —convenient. Built to last, of the best material.

Get our new illustrated circular and learn more about this Price of Production.

P. B. Yates Machine Co. Ltd.

Hamilton, Ontario



Crescent Universal Woodworker

SAVES TIME AND EARNS MONEY

To the builder and contractor contemplating large building operations the Crescent Universal woodworker will mean a large saving in mill work, besides the convenience of having material cut and finished on the job when and where they are wanted. The sawyer's time alone will pay for the machine in a short while. The avoidance of delays which this machine makes possible also results in very important savings, as it assures that the job will not be held up for lack of material from the mill.

Every Builder should have this Money-making Machine

Standard equipment includes—Band Saw, Saw Table, Jointer, Boring Machine and Shaper. A number of other attachments can be added to increase the scope and usefulness of the machine. Floor space is limited and power required for operation moderate.

Write for further information.

The Shimer Round Safety Cylinder with High Speed Knives

A Round Safety Cylinder that will Appeal to the Buyer and the User for three Reasons:

The first is our adjusting nut for setting the knives. It is the only cylinder with properly located adjusting nuts for setting the knives, which, with our way, can be set to 1-1000 of an inch.

The second is our way of holding the knife without tapping into the head.

The third is the correct angle of cut for the knives.

Made for Any of the Different Makers' Machines and in Any Length Cylinder.

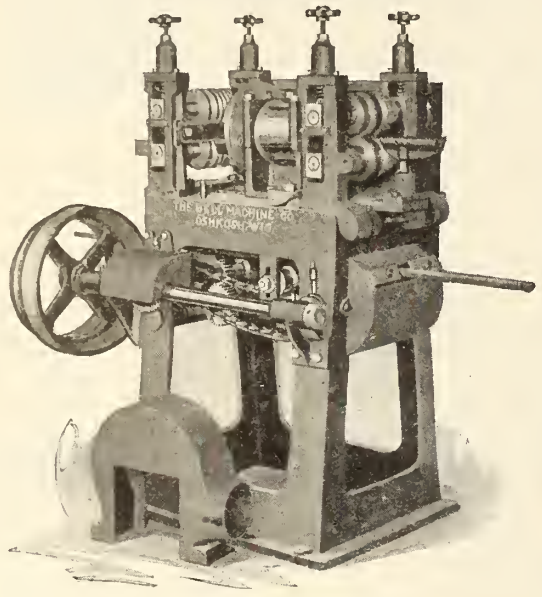
Make Your Own Dowels With the "BELL" Machines

The Fastest and Most Practical Equipment For the Purpose



Adjustable Rod and Dowel Machine

The fastest dowel machine in the world.

Constructed to withstand the heavy and constant strain to which this type of machine is subjected.

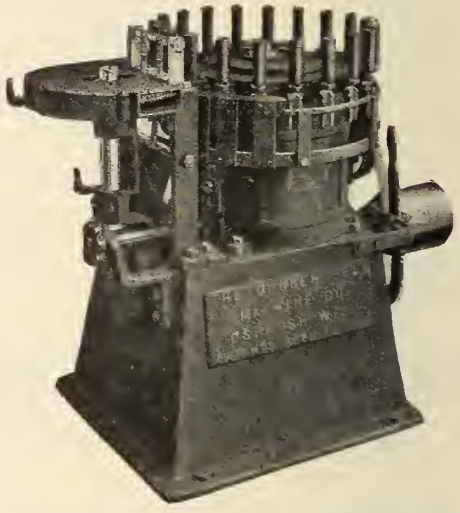
Equipped with a universal four-knife cutter head adjustable to turn rods of all diameters from ¼" to 2" in either plain, spiral groove, longitudinal groove, or imitation reed wind. Special machine for turning rods of larger size.

Cutter-head mandrel is mounted at each end in ball-bearings of the highest grade.

Out-going feed rolls have combination of grooves so that many sizes can be made without changing feed rolls. The in-going feed rolls are adjustable for all sizes of squares.

Will work stock as short as 4½ inches.

Furnished with countershaft or motor drive.



Dowel Cutting Off and Pointing Machine

This machine is for cutting off and pointing dowel pins from long rods.

It will cut and point dowel pins of all diameters up to ¾", and in any length up to 6 inches.

Capacity of this machine is from 300 to 400 pins a minute. Any boy can operate it.

All working parts are completely enclosed and thus protected from dust and dirt.

Absolutely no danger to operator.

The floor space required by this machine is only 22" x 36".

Tight and loose pulleys on machine.

Furnished with belt or motor drive.

MANUFACTURED BY

The Bell Machine Company

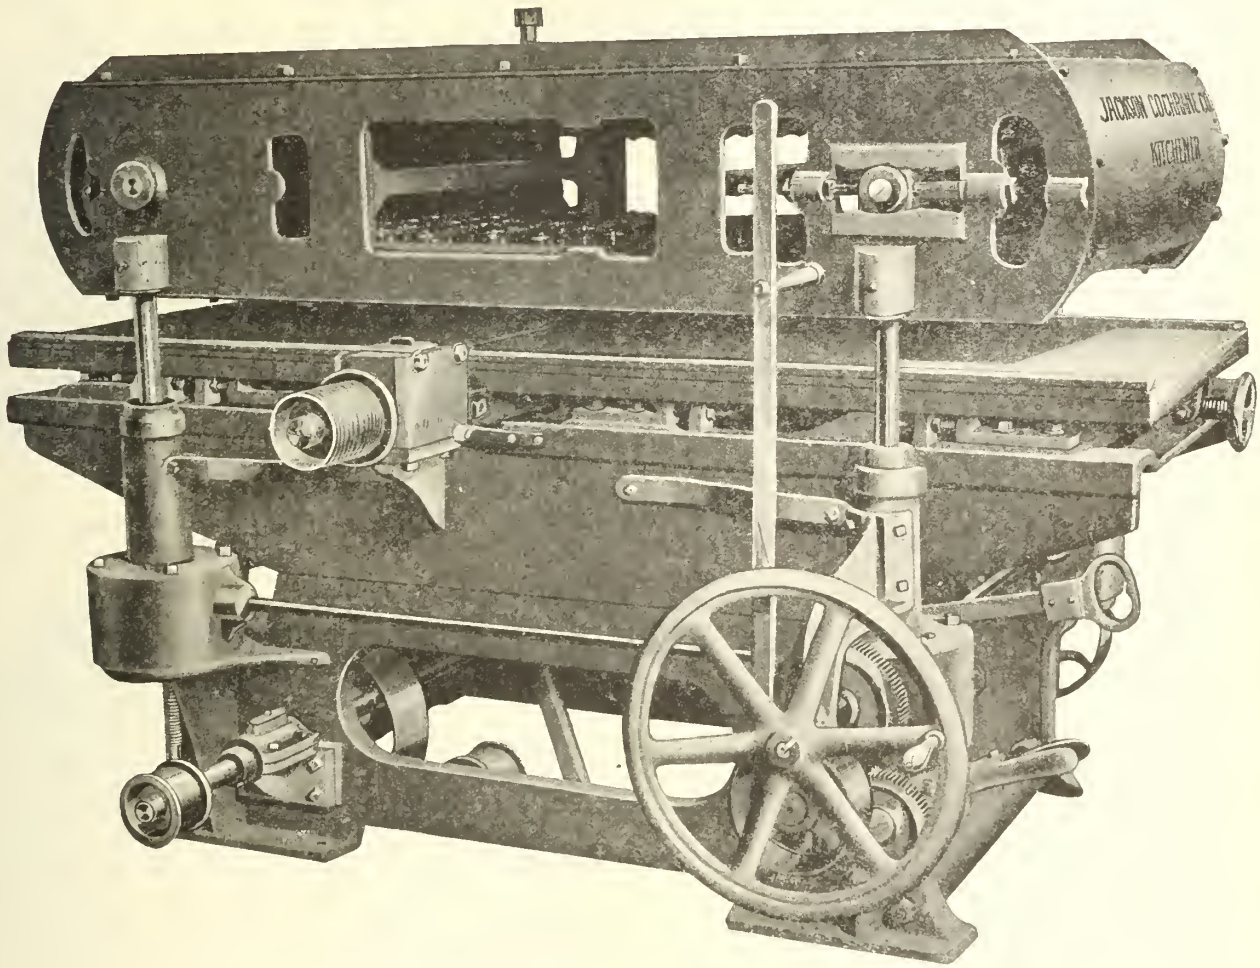
For Canada: THE A. R. WILLIAMS MACHINERY CO. LTD., Montreal, Toronto, Winnipeg

"The Best Equipment Possible for the Work it is Intended to Do"

—*Says Panels, Limited*

of Southampton, Ont.



This machine not only increases production while lowering operating costs but entirely eliminates the dangers to which the operator of the old style buzz planer was subjected.

Just consider these facts:

It handles stock of any dimension, hard or soft, at four times the speed of the old method; occupies but one fourth the space required by four hand jointers; requires but one-fifth of the sharpening of the knives as the hand fed jointer and is easily operated by two boys.

These facts we shall be glad to prove to anyone interested in such a machine.

Satisfaction at Home

Ontario and Quebec users of

National Kilns

say:

"We have just completed the second lot of lumber, dried in your new kiln and we are so delighted with the operation that we cannot refrain from writing to express our apreciation.

As you know, we have had several kilns in the past, of indifferent efficiency, and when this job was installed, we spared no expense in living up to the specifications demanded by you. The results have justified everything we have done, and we wish to say that we can heartily recommend this kiln to any prospective customer."—JAMES MALCOLM, President, THE ANDREW MALCOLM FURNITURE COMPANY, LTD., Kincardine, Ontario. (Manufacturers of Furniture.)

"We have no trouble in drying our lumber perfectly, in very short time, and with practically no waste in drying."—O. E. VARETTE, President, HILL-CLARK-FRANCIS, LTD., New Liskeard, Ontario. (Manufacturers of lumber, millwork and Builders' Supplies.)

"It gives me great pleasure to inform you that our NATIONAL kilns are working perfectly in every particular.

As you know, we have been operating our NATIONAL kilns for about three years, and we find them to be working better every day."—N. A. McLEAN, Supt. Body Plant and L. W. FERGUSON, Dry Kiln Operator, GENERAL MOTORS OF CANADA, LTD., Oshawa, Ontario.

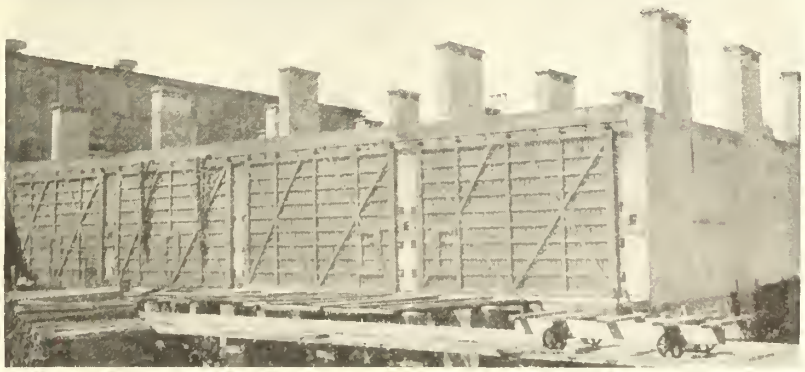
"In connection with your inquiry regarding the kiln that we had installed by you last winter, we beg to state that it is giving us perfect satisfaction and we have found it to do better work than your representative said it would in the first place.

We have been in the lumber business since 1869 and have tried a good many different types of kilns, and are getting better results from yours than from any we have had in the past."—W. T. PIGGOTT, WALTER T. PIGGOTT LUMBER COMPANY, Windsor, Ontario.

"It gives me pleasure to inform you that our NATIONAL KILNS are working perfectly, in every particular.

As you know, our kilns are equipped with all your automatic control devices, such as the automatic water supply tanks, dry bulb thermostat, wet bulb thermostat, scalometers, recording thermometers, door carriers, etc."—J. J. McINTOSH, Supt. RUBBERSET COMPANY, LTD., Gravenhurst, Ontario. (Manufacturers of brushes.)

"Nous devons aussi vous dire que nous sommes satisfaits de l'installation de notre nouveau sechoir."—G. A. ROY, Gerant, INTERPROVINCIALE, LTEE., St. Pie, Quebec. (Manufacturers of caskets.)



Why not follow their example and also be satisfied?

Why experiment?

The Economy and Efficiency of Kiln Temperature Control

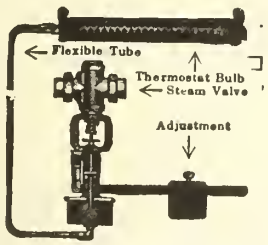
AN unvarying temperature in the Dry Kiln is of the utmost importance. Every inch of green wood has cost you real money and represents two values—raw value and finished value. Don't allow fluctuating kiln temperature to tamper with these values. Equip your kilns with

Powers Heat Regulators

As long as steam pressure is maintained Powers Regulators operate. Their operation insures correct kiln temperatures; saves fuel by using only necessary heat; saves labor by releasing men from watching thermometers and valves; saves material by cutting down the loss from case hardening, warping, and checking. Moreover, they also **Speed Up The Drying By Fully 25 Per Cent.**

Not An Experiment

"Play Safe." Install the Powers Heat Regulator—the product of more than thirty years of experience in Automatic temperature control. During our experience, we have gathered some very profitable information for the woodworking industry. Let us show you how to save money in your kilns, glue pots, drying rooms, hot water tanks, etc.



The Powers Regulator No. 15
Specially designed to control temperature in dry kilns, ovens, varnish and dry rooms, etc. Requires no outside power for its operation.

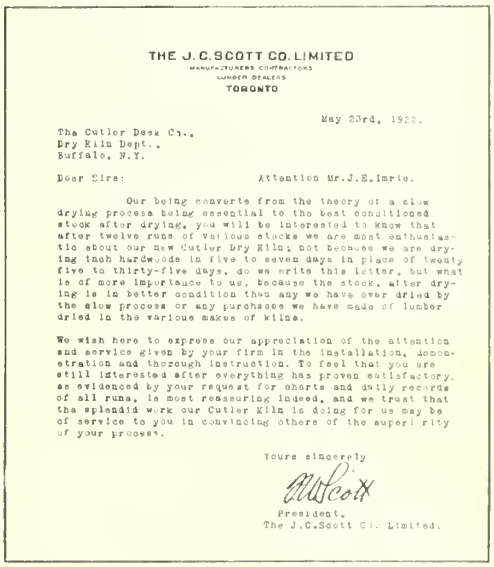
2 Cutler Dry Kilns

Will produce as much dry lumber as 4 of any other kiln

THE new Cutler Dry Kiln is very greatly different from other kilns. It embodies a new and original principle (patented.) Its value to you is not only a two-to-one saving in installation cost, but a greatly improved quality of drying. Read Mr. Scott's letter.



THE J.C.SCOTT CO.LIMITED
MANUFACTURERS CONTRACTORS
LUMBER DEALERS
TORONTO

May 23rd, 1922.

The Cutler Desk Co.,
Dry Kiln Dept.,
Buffalo, N.Y.

Dear Sirs: Attention Mr.J.E.Imrie.

Our being converts from the theory of a slow drying process being essential to the best conditioned stock after drying, you will be interested to know that after twelve runs of various stocks we are most enthusiastic about our new Cutler Dry Kiln; not because we are drying inch hardwoods in five to seven days in place of twenty five to thirty-five days, do we write this letter, but what is of more importance to us, because the stock, after drying is in better condition than any we have ever dried by the slow process or any purchases we have made of lumber dried in the various makes of kilns.

We wish here to express our appreciation of the attention and service given by your firm in the installation, demonstration and thorough instruction. To feel that you are still interested after everything has proven satisfactory, as evidenced by your request for charts and daily records of all runs, is most reassuring indeed, and we trust that the splendid work our Cutler Kiln is doing for us may be of service to you in convincing others of the superiority of your process.

Yours sincerely
W.M.Scott
President,
The J.C.Scott Co. Limited.

A 35 ft. 1 car capacity Cutler Dry Kiln costs approximately $4200, complete, and has a yearly capacity of over a million board feet 4-4 hardwoods. Let us tell you how and why. Write or wire our Planning Engineer. Consult him for definite proposal. No obligation.

Reg. U.S. Pat. Off.

OF COURSE YOU KNOW

General Office and Factory

"QUALITY" if applied in its truest sense to a vegetable glue means a combination of quality workmanship plus quality materials. The best materials produced could be present in the glue, yet it might cause all sorts of trouble in plywood construction, due to the absence of that skill in manufacturing which can only come from years of vegetable glue making experience.

PERKINS 183 represents years of progress by the organization which discovered vegetable glue. Time always has been the deciding factor that proves the ability of a manufacurer to produce a dependable product that will enable the consumer to realize a maximum return for his investment.

Patents covering Perkins Glue have been held valid and infringed by the United States Circuit Court of Appeals. Patents have also been granted in Canada, Great Britain, Germany, France, Belgium, Italy and other foreign countries.

A little talk on

Langslow Limited

and the

Rice Lake Canoe Company

at Cobourg, Ont.

The Langslow Limited Plant

C.M.C. $33,000 Worth o

In The Canada Machinery

IT is to be conceded that a firm with the long and successful experience in furniture manufacture that has be the lot of the Langslow-Fowler Company of Rochester, N.Y., must know good machinery. If they did no is questionable if they would have attained the position in the trade which they now enjoy. They possi would not have been prepared to build and equip the splendid Canadian branch factories which they now op ate at Cobourg, Ontario.

Langslow's do know good machinery. They have on their staff competent, critical and practical men u whose advice the equipment for their Cobourg factories has been purchased.

Considering this, we feel gratified to be able to refer to these two practically entire equipments of new C.M machines selected by them after the most painstaking and comparative investigation. Nothing but the b would suit them and in C.M.C. machines they found it. It is the more flattering to us when we consider the ini installation in the Langslow Limited plant which was ordered during the autumn of 1920 gave such excell service that when it was necessary for them to increase their production and to equip their newly erected "F Lake Canoe" plant in the fall of 1921, they came directly to us to fill their new requirements. "The proof of pudding was the eating."

All machines listed are giving excellent satisfaction and we are proud to say that we can confidently r you to Langslow, Limited, as to the performance of any one of them.

The illustrations of these two pages show a few of the principal machines in actual operation.

Some of the other machines installed in these plants are shown on the last page of this advertisement.

Pergola and lattice-work trellis on a country estate near Aurora, Illinois.
Monite Water-proof Glue used exclusively

MONITE Waterproof Glue

Is used wherever durability and permanent beauty are demanded. Boil it, bake it, soak it or freeze it—

MONITE STICKS TO ITS JOB.

All Outdoor Work Glued With MONITE

"The staves of all columns, their caps and bases, and all exterior work produced by us is put together with cold water waterproof glue"—p. 4, Catalog No. 47, Hartman-Sanders Co., Chicago and New York.

And that "cold water waterproof glue" is Monite Waterproof Glue—adopted after thorough tests of other glues, for exclusive use.

The Hartman-Sanders Company of Chicago and New York, builders of the famous Koll's Patent Lock-Joint Staved Wood Columns, veneered columns, porch materials, lattice work, art fences, pergolas and garden furniture find Monite Waterproof Glue a necessity for maintaining the beauty that they build into their work.

From New England to the Hawaiian Islands, the Hartman-Sanders Company have added their architectural adornments to notable public buildings like the Old Lyme Church in Connecticut, the Moana Hotel, Hawaii—and to beautiful residences and estates like that of E. J. Lehmann at Lake Villa, Illinois.

From porch and pergola to garden seat, all the Hartman-Sanders exterior work uses Monite Waterproof Glue exclusively. And their work is much sought after by architects and builders for it combines beauty with permanence.

Monite Waterproof Glue withstands all exterior weather conditions, rain and fog, zero, blizzards or blistering sun. It is equally effective for interior woodwork or furniture, enduring extremes of heat and cold or dry and damp.

Manufacturers, builders, dealers, or housewives who have had trouble with loosened glue joints or veneer with any form of furniture or mill work should write for the Monite story. An interesting vest-pocket panel of plywood glued with Monite will be sent free.

Boil it, bake it, soak it or freeze it—Monite sticks to its job.

Caster Performance Is Taken for Granted

Casters show their great importance least when working well. They attract little attention while they perform perfectly.

But the casters are there, working every time the piece is moved. Hence the need of dependable equipment.

If they are efficient, well-built casters like **Efemco** you will scarcely be aware of their presence.

Efemco Casters will give lifetime service wherever they are applied and there is a kind designed for every use.

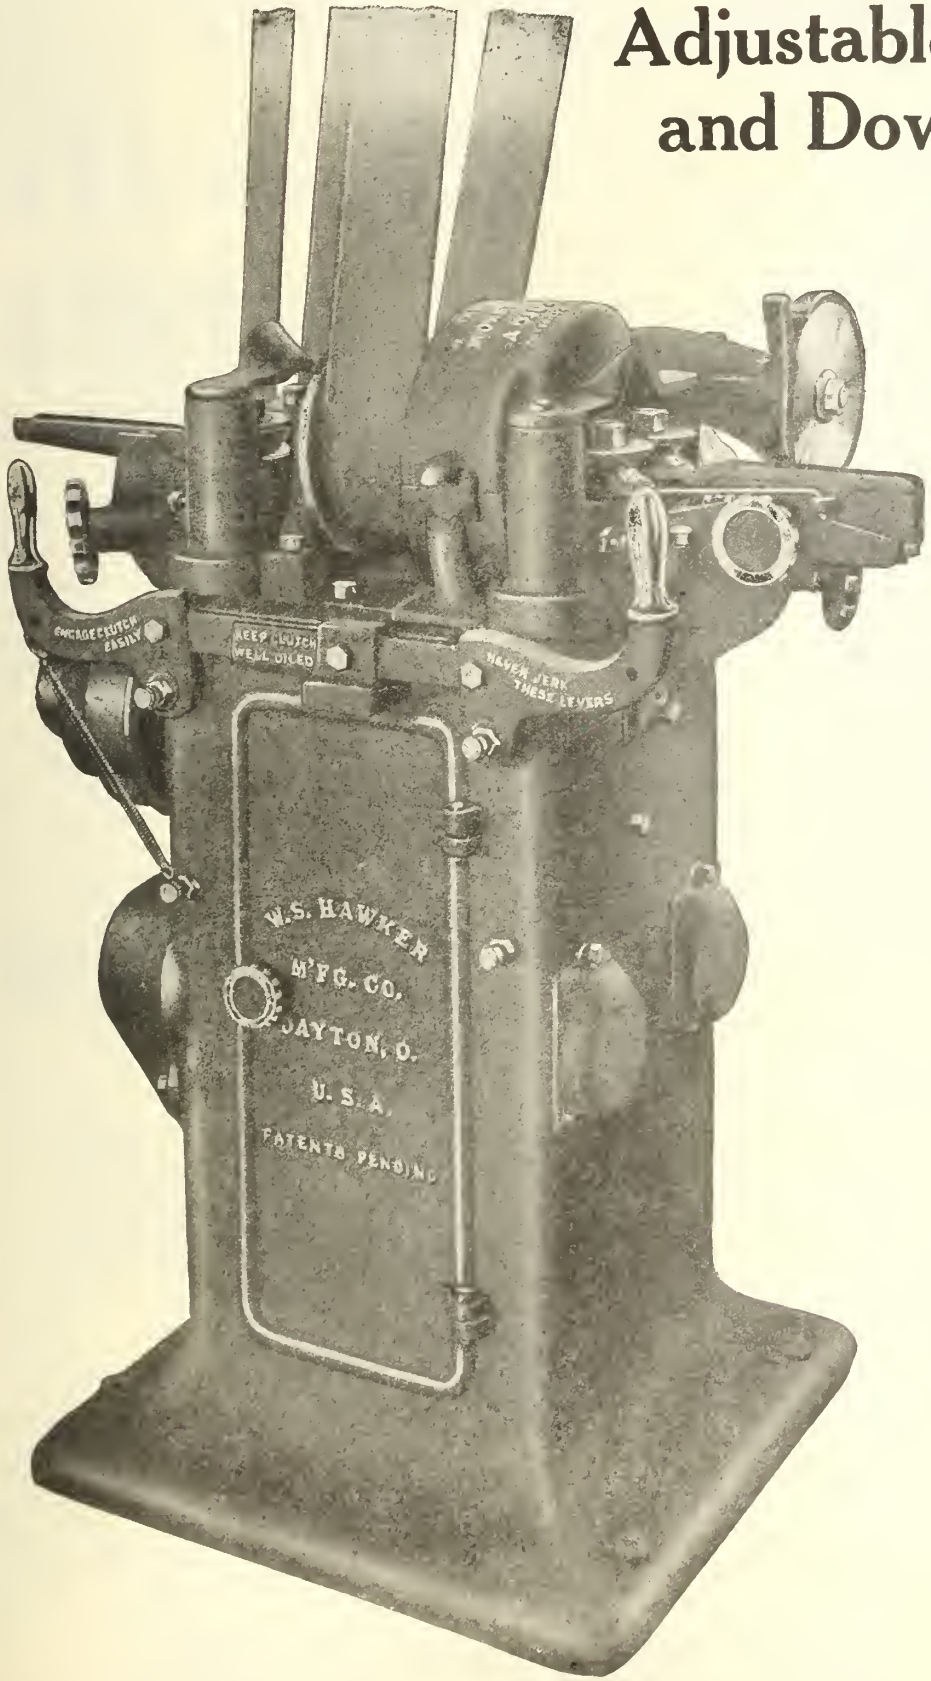
The Money Maker— Adjustable Rod and Dowel Machine



Capacity 30,000 to 40,000 lineal ft. per ten hours on 7/8 or 15/16 mop or sweeper handle stock.
If you are using any dowel machine of less capacity, figure your daily losses in labor and business.
Write us what dowel sizes you turn, and whether hard or soft wood. Ask for our demonstration proposition to show you how to double your production of dowel stock at the same labor cost.

The machine that is sent under a guarantee to show you a gain of from 100 to 400 per cent before you buy it.
The improved dowel machine that 90 per cent of the largest and oldest machinery builders and dealers now endorse and recommend in preference to the solid chuck machines they themselves previously built.
One cutter head turns from ¼-in. to 2-in. diameter.
Turns hard or soft wood equally well.
Handles heavy, oversized squares.
No choking of the cutter head.
Smooth stock.
Accurate sizes.
Works stock as short as five inches.
Rolls automatically center variations in squares.
Machines built to turn from ⅛ to 6-in.
We want to hear from every user of a solid chuck dowel machine.
We can save you from one dollar out of every two, to four out of every five that the operation of solid chuck machines costs you.
Engagements for competitive test solicited.
Formal orders not solicited. All sales made after demonstration.

The only question is, are you willing to cut cost of your dowel turning to one-half or one-third of what it costs with any make of solid chuck machine?
Machine delivers the goods before you buy.
State conditions of stock closely
Special conditions require special equipment.

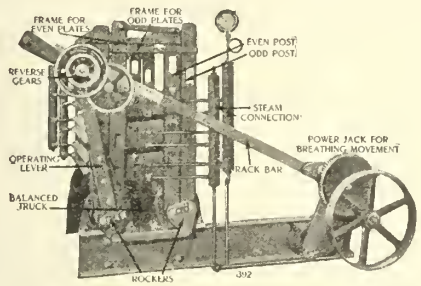
It Pays to Install a "Merit" Re-drier



Bulletin No. 70-C.W.

Re-drying was not practiced to any extent 15 years ago when the "Merit" re-drier made its appearance on the market. Today very few glue rooms take a chance on veneer that has not been re-dried under hot plates and very few plants using veneer have neglected to install a "Merit" re-drier. This machine flattens the veneer and makes it absolutely bone dry. It takes very little steam and is operated by a 2 h.p. motor. It saves glue, simplifies taping and jointing and insures success in the finished product. It is made in several sizes of plate and starting with 4 plates, a machine can later be expanded to 12 or 16 plates.

A Statement

by the

Hardwood Manufacturers' Institute

to all

Users of Hardwood Lumber

We are in position to help you cut your material and labor costs—definitely, intelligently and permanently.

The biggest "profit eater" in your business and ours is WASTE. As a matter of Public Service, in which is bound up our individual advantage and legitimate profit, we are carrying still further forward a sound policy of WASTE ELIMINATION.

This policy in our own production is the beginning of its application for your advantage to YOUR PRODUCTION PROBLEMS.

In a word, we can and will hook our production closer to your needs on the basis that, though you are buyers and we are sellers, there is a common interest which we both must serve. That is the interest of the twenty-one million families in the United States who spend some forty-five billions of dollars annually that PAYS EVERYBODY FOR EVERYTHING.

Insead of your buying a stated quantity of certain grades and sizes, and including the labor and material waste as inevitable burdens, let us counsel together so that we can make our product fit closer to your needs.

There are tremendous changes at work in all lines of business—so far-reaching that most men do not yet appraise their power and extent.

This power was as inevitable as the tide—and is just as resistless. We of the hardwood manufacturing industry of America are at the forefront of this new swing in business, for we realize clearly that only by the utmost service in addition to the production of the best possible Hardwood lumber can we assure the stability, progress and prosperity of our industry.

Because your interests and ours tie in closely on this basic principle, we offer our services and invite you to counsel with us in arriving at the best kind, grade and size of hardwood that will best meet your needs for specific purposes.

THIS OFFER AND INVITATION IS BASED NOT ON A THEORY OR A "HOPE" BUT UPON THE GROWING PROOFS THAT ARE THE RESULT OF OUR ACTUAL WORK. IT IS BEING ACCEPTED IN A RAPIDLY MULTIPLYING NUMBER OF CASES AND, WHEREVER IT IS TRIED IT CUTS COSTS, SAVES WASTE AND INSURES ECONOMIES.

WE INVITE FRANK CORRESPONDENCE AND ARE PREPARED TO RESPOND PROMPTLY, CANDIDLY AND WITH PRACTICAL HELPFULNESS IN EACH INDIVIDUAL CASE.

Behr's Garnet Cloth Standard for Belt Sanders

The backing is made practically stretchless, by a special finishing process, exclusive with us.

The glue is the most suitable obtainable—its cost is a secondary consideration.

Garnet kernels—clean, hard, sharp and evenly graded—are applied in just the correct volume to give the fastest, smoothest and longest cut possible.

These are the qualities that have made Behr's Garnet Cloth the standard for thirty seven years.

Samples for trials on your own work sent without charge; please specify grades, width and weight of backing desired.

From Tree to Consumer

For nearly thirty years the Chapman and Dewey Lumber Company has cut the timber from its own hardwood lands in the famous St. Francis delta region of Arkansas, sawn it in its own mills and sold the lumber through its own offices. From the cutting of the trees until the last board is loaded on the cars this company handles its entire product. The result is low cost of operation and economy in selling —distinct savings which the customers of this company enjoy. When you buy from Chapman-Dewey you buy direct from the tree.

This Company can offer at this time some exceptional quotations on Hardwoods for a great variety of manufacturing purposes. Wire our expense for quotations.

Buy Walnut Now

Every Size in Walnut Lumber Now in Stock to Meet Your Needs

Reviving business and the increasing trend toward Walnut is bringing steadily increasing demand for Walnut lumber.

Mills like all other businesses, have been buying cautiously, stocks throughout the country below the normal. Rapid increase in buying may bring shortages of the items you most desire.

We, therefore, advise your looking over your stocks and anticipating your needs now, while conditions are most favorable.

Just at the present moment we can supply on short notice practically any need in Walnut—every piece of the selected quality and perfect cure that have made Iowa Walnut the first choice of some of the best cabinet makers in America.

Write or wire your needs to us and let us quote you on Iowa Walnut—in both lumber and veneers—the best in American Walnut.

Since 1883

THIRTY-NINE years ago Henry Pedwell founded the Pedwell Lumber interests.

In those pioneer days the furniture trade was but a tithe of what it is today. The automobile industry was unthought of. And hardwoods were for the most part put to inconsequential use.

Yet today Canadian Hardwoods find their way not only to Canadian and American factories, but to European markets as well.

The Pedwell Hardwood Lumber Company has enjoyed marked success during these few decades. Its clientele reaches West of the Rockies, South of the Line and across the Atlantic.

The four-square dealing and courteous service, which today is so much a part of our policy, has been largely responsible for this phenomenal growth.

Pedwell service means something to Pedwell clients. It is significant that some of our business friends of 1883 are today being served by us.

The Pedwell Hardwood Lumber Company

FOOT SPADINA AVENUE : : TORONTO

Specialty E C & S *Birch*

This desk was designed for durability; it is made of

CLARK'S CANADIAN BIRCH

The beauty of Canadian Birch is unquestioned in the minds of many large manufacturers who use it in executing their designs for the most exquisite of furniture.

Canadian Birch is also recognized as the ideal wood where durability must be combined with good appearance. One of the large American makers chooses Clark's Birch for school desks —a product demanding the utmost in durability of its materials.

Is Your Kiln Drying Satisfactory?

In making the rounds of various plants and factories the "Canadian Woodworker" often hears stories of how so and so lost a whole kiln load of lumber, valued at more than a thousand dollars or that another firm is experiencing trouble due to open joints and warping, while a third finds that in spite of his best efforts the lumber will check while being treated and so on down the whole list of kiln drying troubles and after effects. It would seem that the manufacturer who is not bothered with kiln drying troubles and those due to imperfect seasoning, is the exception rather than the rule.

It was not so very long ago that all this was taken as a matter of course. Woodworkers seemed to be resigned to the belief that while such troubles were annoying and costly in the extreme, they were unavoidable and must therefore be accepted with the best grace possible. However, that attitude has undergone a rather complete change, due largely to the advance which has been made in the theory and practice of kiln drying and to-day woodworkers see the folly of their old acquiescent attitude, and as a result they are attempting to grapple with their drying problems in a more or less whole-hearted manner.

In this they are handicapped because of a lack of knowledge of the fundamentals which underlie kiln drying as advocated and practiced to-day. True, many woodworkers have remodelled their kiln drying equipment or even put in a new battery of kilns, but the operation of the kiln is more or less perfunctory or rule of thumb. That is, it is customary to follow rigidly a set of rules which is supposed to cover drying of all ordinary woods but which does not make allowance for the unusual or out-of-the-ordinary condition or occurrences or which does not take into consideration the individual peculiarities of each installation of kilns and of each charge of lumber dried. Until all kilns are identical in every way, not only as to physical characteristics but in their operation, and until all lumber is graded so uniformly that each charge will be exactly the same as the preceding and the succeeding ones—something which is absolutely absurd to even consider—until such a time the operation of a kiln by rules will always be a source of annoyance and expense.

The suggestion that the operator is more important than the equipment, that poor equipment in the hands of a good operator is better than good equipment in charge of a poor operator is true and is worth repeating, for until it is accepted in its entirety and acted upon, trouble is bound to be experienced. If the present operator is not susceptible to new ideas, if he thinks he knows it all and is not willing to study and learn, an effort should be made to secure a man who knows how and why, who knows how lumber dries, how the drying may be controlled, the cause of various troubles and how they may be prevented and who in other ways is able to operate the kiln intelligently. It is the operator who counts. A good operator is worth a good salary for he can save a lot of trouble and expense.

Recently, furniture manufacturers have evinced a decided interest in this important phase of woodworking. Working in close co-operation with the University of Toronto, the Furniture Manufacturers' Association has been instrumental in securing the services of a trained research man who has been visiting various plants, studying conditions and methods as found in connection with the drying of lumber and assisting in every way he can. This work has been productive of real tangible results.

Realizing the need for assistance in this direction, we understand that certain manufacturers of hardwood lumber have subscribed to a special technical lumber service which they are offering free to their customers. This is a little broader than a strictly kiln drying service as it includes air drying, the handling of lumber, kiln drying and the suitability of various grades of lumber. This service includes the assistance of trained men who will visit plants free of charge and assist in improving the kiln drying and lumber handling methods and in overcoming any troubles which may be experienced in the seasoning and drying or in subsequent manufacturing operations where the question of suitability of grade or condition of the stock enters.

We all complain of the shortness of time, and yet have much more than we know what to do with.

High Core Production at Lowest Cost

How the Wood-Mosaic Co. Have Developed a Highly Efficient Gluing Department, Reduced Costs and Increased Production — Clamp Carriers an Important Feature of the Plant Equipment

By R. W. Burns*

Considerable interest has been evidenced in the article "Development of Edge Gluing" which appeared in the February number of the "Canadian Woodworker." This interest seems to center around the high production obtained by the Wood Mosaic Co., of Louisville, Kentucky, on their ten Taylor clamp carriers. It is therefore to fulfill the desire of the trade for a further explanation of their methods that this article is published.

The report of one week's core production on two Taylor clamp carriers at Wood-Mosaic Co. was published in the article mentioned above, which when analyzed, showed 20½ to 24 revolutions per 40 section machine per nine-hour day, with an accompanying production of from a minimum of 1,705 to a maximum of 3,150 finished cores per machine and a minimum of 6,528 to a maximum of 7,827 surface feet of finished stock per machine per nine-hour day

Routing Well Arranged

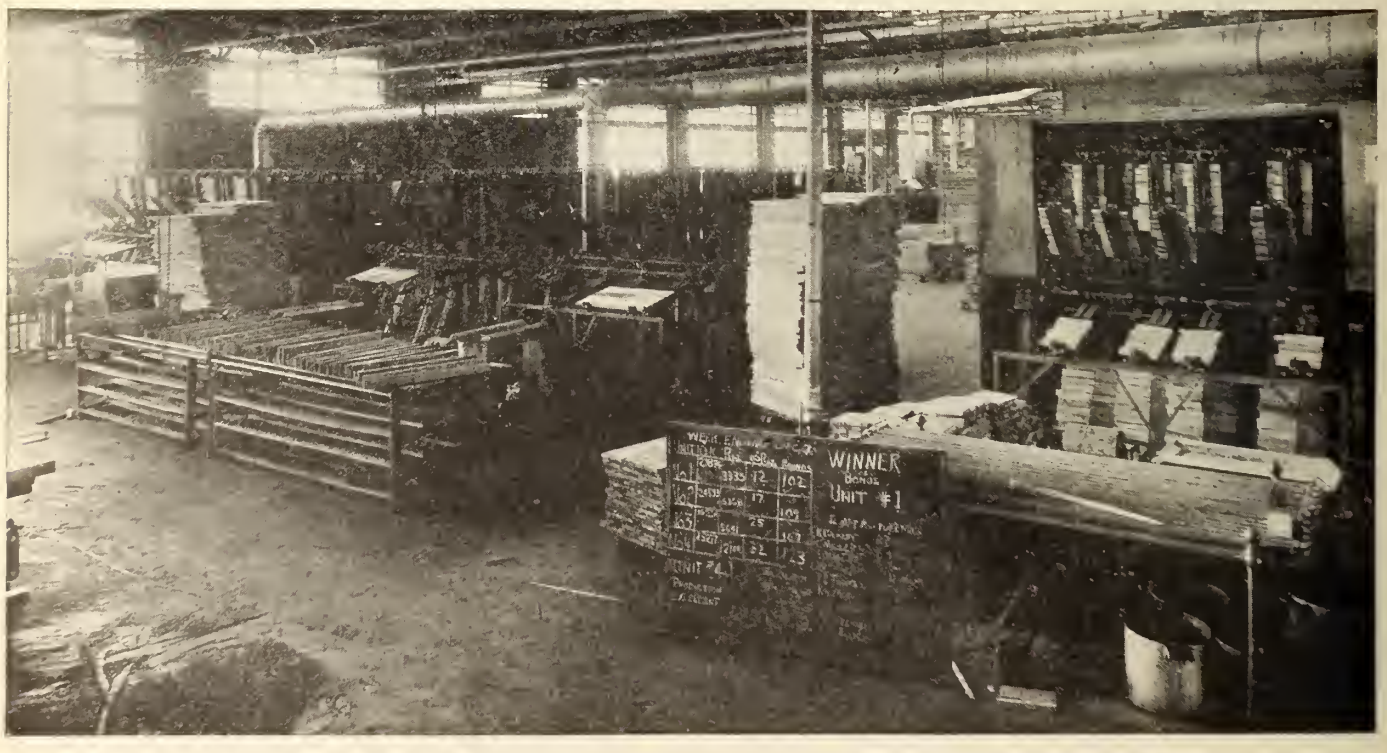
Wood-Mosaic Co. have arranged their machinery so that material travels practically straight through the factory, thus not only making the moving of material efficient but making it possible to locate congestion easily and remedy it quickly. At the extreme end of the factory are the dry kilns with the most modern methods for bringing the lumber to the rip and cut-off saws. From here the stock goes to the matching saws and then passes on to the glue jointers, which are placed one beside the other clear across the factory.

Directly ahead of these jointers is the battery of ten 40-section Taylor clamp carriers. On an average one continuous glue jointer keeps work ahead of one Taylor clamp carrier. The high grade core and top work is all put through the glue jointer per customer's specifications. However, in the past they have glued large quantities of core stock direct from the rip saws.

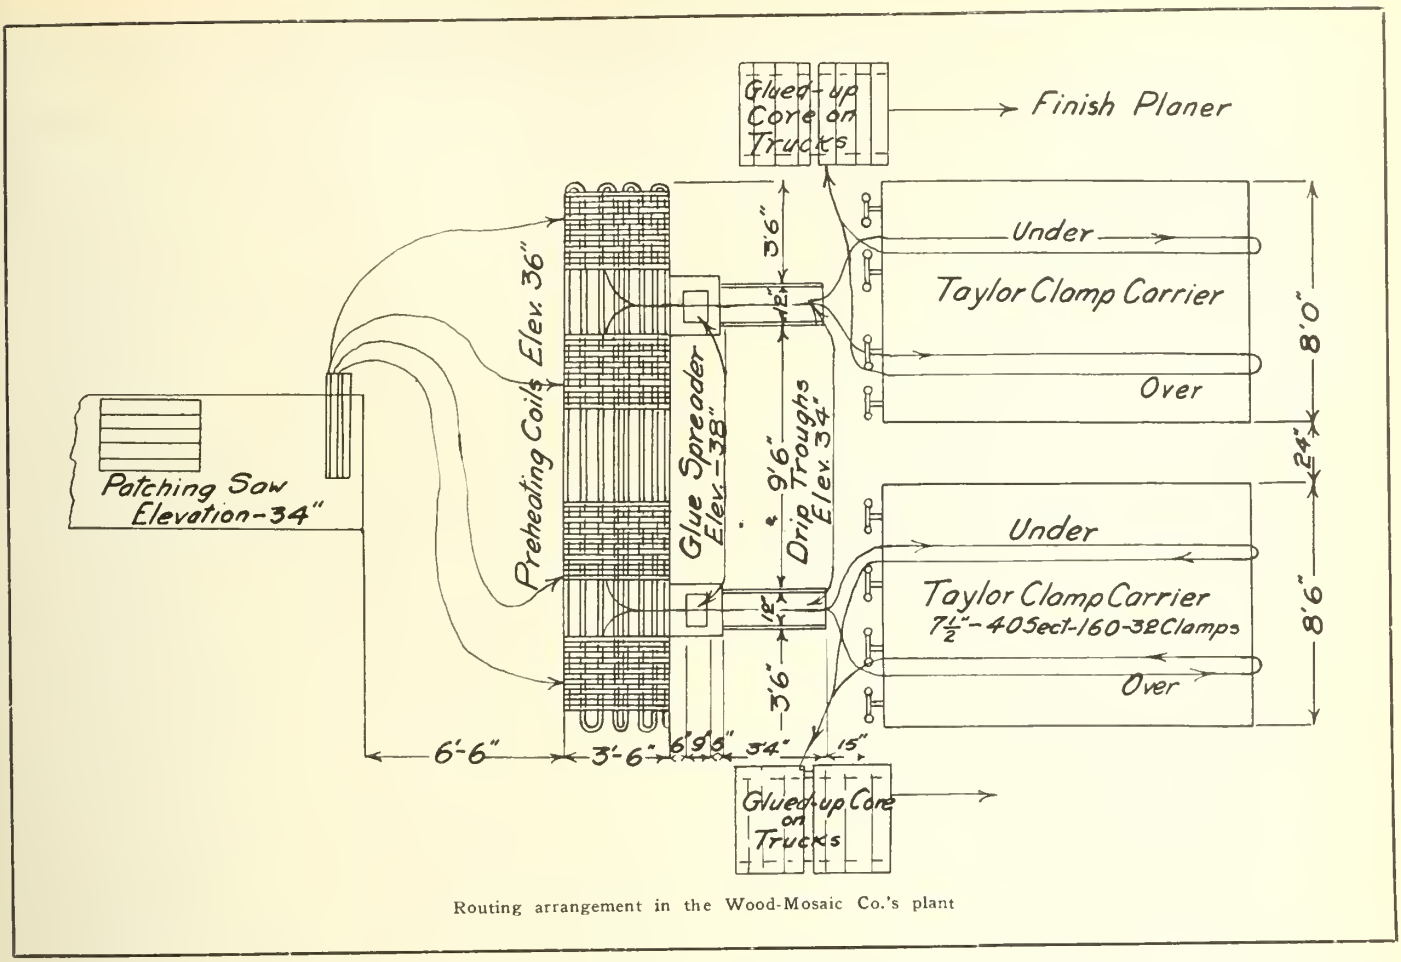
Between the continuous feed glue jointers and the Taylor clamp carriers are preheating coils through which steam passes. These coils are shown in the accompanying layout and are at such an elevation and location as to be conveniently accessible both to the glue jointers and the clamp carriers. The pieces composing each individual core are set on edge as a unit on the preheating coils by the jointer operators. Under these coils are racks for surplus stock.

The layout shows the position of the preheating coils and glue rolls in relation to the clamp carriers. There are two operators to each Taylor clamp carrier. Each operator gets the stock for his core from the heating coils, draws it with one motion of the arms across the glue roll and with a very adroit movement makes the pieces composing his core slide one over the other onto the clamps so that the latter can be immediately tightened. The stock is then pounded down with a mallet, and each operator contributes to turning the carrier to the next section. This turning of the machine is done very easily and much more quickly than a power driven machine because of the

*Of Jas. L. Taylor Mfg. Co., Poughkeepsie, N.Y.



This picture with the one opposite forms a panoramic of the interior of the Wood-Mosaic Co.'s plant



Routing arrangement in the Wood-Mosaic Co.'s plant

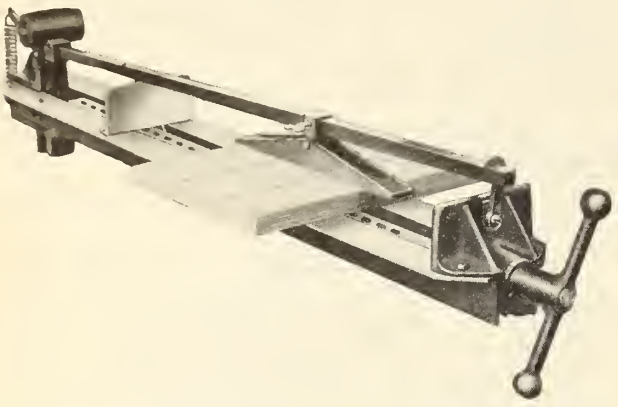
acceleration possible by hand pull and discontinuing the pull at the proper time according to the load. The glued-up stock is then removed from this succeeding section now in front of the operators, each operator removing his own core, but the other operator nearest the aisle piles the two cores on the truck. After being filled these trucks are pushed out of the way and the following day the cores go through the planer. Often when the cores are narrow each operator can insert two cores edge to edge in one set of clamps, in which case the removable pressure bars (shown in cut of clamp) can be quickly inserted and drawn down

Note how the arrangement of the equipment makes for ease and rapidity of handling

to keep the work from buckling when the clamps are tightened. In the case of these narrow cores the production is four cores per section.

Fan Aids Glue Setting

The Wood-Mosaic Co. control the humidity of their plant and keep it uniformly dry, but during the damp days in the warm months when the glue does



The carrier clamp that facilitates gluing operations by the Wood-Mosaic Co.

not have a tendency to set so quickly, they operate a big fan which is located in the center of the factory. This fan is piped above and across the battery of clamp carriers. Between each two machines a pipe leads down to two flaring nozzles. When the fan is operated the air is blown from one of these nozzles directly on the freshly glued cores of one clamp carrier and from the other on the cores in the adjacent machine to help set the glue. In this way, together with high grade animal glue, they can get their work to set satisfactorily in twenty minutes, if necessary.

Wood-Mosaic Co. realize that in order to get good production they must pay their men well, and therefore pay a high enough wage to get good operators. Of course, only good men are allowed to stay on the job. The week is a 50-hour week and the men are paid a bonus for all revolutions of the Taylor clamp carrier over fifty-five (55) per week. This is calculated on a weekly basis to avoid speed and rushing one day and loafing and resting the next.

Rigid Inspection

Before any cores are packed or loaded they are carefully inspected by inspectors employed for that duty only. This inspection on the cores would be considered very good inspection on solid work. Each individual core is inspected on both sides, the joints are tried and on the least indication of an open joint the inspector breaks the core and it is returned for regluing. So rigid is the inspection that sometimes the wood breaks before the joint, when inspected. The good cores are stamped with the inspectors' O. K.

The production obtained by Wood-Mosaic Co. shows to what a high state of efficiency a manufacturer may attain when he concentrates on one product, groups his machines for that product, studies each move to eliminate lost time and material and then puts through such volumes of one size as to make adjustments in his machines infrequent and their operation continuous. The Wood-Mosaic Co. is probably the most modern and efficient plant of its kind in the country.

Fifty Years of Service to the Woodworking Industry — Herman Behr & Co's. Golden Anniversary

An event of considerable interest to the woodworking industry was the celebration on August 7 of the 50th anniversary of the establishment of the firm of Herman Behr & Co., Inc., the well-known manufacturers of sandpapers, whose products have enjoyed a favorable reputation and extensive use by all branches of the wood-using industry. During the half century of its existance the firm has been responsible for several distinct innivations in the manufacture of sandpapers, and it is interesting to sketch the development of the organization, paralleling as it does the growth of the abrasive industry as a whole.

The founder, Mr. Herman Behr, still the active head of the company, was born in Hamburg, Germany, in 1847, and come to the United States at the age of three. After being in business with his father, an importer and manufacturer in a small way, of hardware, he became interested on August 7, 1872, in the manufacture of sandpaper, entering the business with very little knowledge of the process of its manufacture, but relying greatly upon his own ingenuity and experiments, and in fact, making many of his own tools and machines. So well did the business grow, that new quarters had to be secured a year later. From time to time new members were admitted to the firm and in 1911 the company, which had grown by that time to one of the leading houses in the industry, became a corporation under the laws of the state of New York. To-day the plant covers a floor space of 4½ acres at 31-36 Tiffany Place, Brooklyn, with nearly 300 employees in the organization. The company has several branches viz., Chicago, Boston, St. Louis, San Francisco, Grand Rapids, Toronto and London.

Herman Behr & Company has been progressive in all of its undertakings, particularly in developing its own machinery and manufacturing processes to the point where the production of sand papers has become a science. During the fifty years of its existence, the firm has put several distinct innovations on the market. It made the first perfect pouncing paper in the United States. It introduced the first garnet or red sand abrasive paper in the world. Later it made the first flexible cloth belts of abrasive and followed this with the first successful aluminous oxide coated cloth discs for metal grinding . The most recent advancement in the improvement of sand paper is marked by the invention in 1918 of Behr's Openkote Process of putting sand on paper.

The company has been equally progressive in conserving the health, safety, comfort and interest of its employees. its humane welfare work is evidenced by the most improved sanitary conditions in plant and office, voluntary protection for its employees against sickness and want through health insurance, compensation insurance and life insurance. Herman Behr & Co., were among the first to recognize that their obligations to employees did not end with the weekly pay envelope, by the institution of a bonus or profit sharing arrangement, whereby every member of the organization shares to some extent in the profits of the company. The company also enjoys the pleasure of having had men in its employ for forty years and has been dealing with some customers for nearly fifty years and purchasing goods from some concerns for nearly that length of time.

Standardizing Woodworking Operations

Production Knowledge, Which Means Knowing What Your Output Should be, Instead of What It Is, Is the Logical Basis on Which Costs Can Be Lowered and Production Increased—The Application of Time Standards

By L. R. Wright*

"Knowledge" is absolutely essential to the continued success of any industrial or commercial enterprise. By knowledge is meant accurate information pertaining to every phase of the activity of the various divisions of the organization. For instance, accurate cost knowledge is the only true foundation on which the selling price should be based. Similarly, production knowledge is the only logical basis upon which production can be increased and costs decreased. By production knowledge is meant a knowledge of the maximum, not actual, capacity of men and machines covering various classes of work. It is only when this maximum output is known that an intelligent effort can be made to attain the highest degree of productiveness.

It is simple enough for a manufacturer to check over his cost figures, that is, if he is fortunate enough to have them available, and ascertain the output of any machine or workman covering certain classes of work. When he has done this he is not much better informed than before securing this information, for such data does not give any indication of what the output should be. He may rest content thinking he is getting all possible from his equipment or his employees and thus neglect to bend every effort to improve conditions and bring production up somewhere near to what it should be.

Development of Standards of Production

It is only during recent years that a determined effort has been made to develop standards of productiveness for men and equipment in the woodworking industry and in doing this a large number of intricate problems were encountered and solved. To begin with, while all woodworking operations, that is machine operations, may be divided into cutting and handling time, yet on certain classes of work it is the handling time which limits the production of the equipment, whereas on a different class of work the feed or capacity of the machine controls the output. On the sticker, for instance, except when extremely short pieces are being fed through, the rate of feed is the controlling factor and while the rates vary for different classes of work the output should always be directly proportionate to the feed carried. However, when we consider the planer or drum sander we are confronted with another set of conditions. On stock exceeding half the width of the bed, so that only one piece can be fed through at a time, the feed is again the controlling factor, except, as noted above, in the case of extremely short stock, when handling becomes the deciding factor. On another group of sizes a combination of handling time, which depends on length, width and thickness for an employee can pick up a greater number of short pieces than he can of longer lengths or a greater number of thin pieces than if he were working with thicker material, and feed rates must be considered in determining the standard output. With the smallest sizes it is entirely a question of handling, for it stands to reason that an operator could not keep the bed of the machine full when putting through small pieces.

Carrying out this line of reasoning it becomes apparent that it should not take any longer to lift a certain sized piece from a truck and place it on the planer bed than it does to place the same sized piece on the bandsaw or shaper table and further that it should not take any longer in one plant than in another. If it does, there is something wrong somewhere, either with the workmen, the layout of equipment, the way the material is brought up and handled or in some other way. Similarly, similar machines in different plants running at the same cutter head speeds and carrying the same feed should have the same degree of productiveness on the same classes of work. If not, there may be some physical reason.

Systems Applicable to All Operations

Working along in this direction in many plants and over a period of time it has been possible to establish definite standards of productiveness for men, machines, departments and even whole plants. Of course, it was not all as simple as outlined above, for many machines and many operations presented real problems, but in every case it was found possible to reduce the work to certain basic standards which would apply to all plants covering different classes of work. Not only have these standards been developed and applied in connection with machine operations but they have been applied to veneering, assembling, finishing and packing operations so that to-day the whole work of producing furniture from the time the lumber is received to the shipping of the finished product can be carried out on the basis of definitely known time standards.

Now as to the practical application of these standard times, knowing the goal is half the battle. As was suggested in the opening paragraph, production knowledge, which means knowing what the output should be instead of what it is, is the only logical basis upon which costs can be lowered and production increased. These basic time standards provide a basis of comparison by which the relative degree of productiveness of a machine, workman or department may be judged. If found to be low, the problem then resolves itself into ascertaining the reason and applying the remedy and thus bring the output of that particular operation to as near the standard as conditions permit. To make a broader application, a common basis or a common language is established by which the productiveness of workmen and equipment in different plants, and even the plants themselves, may be compared.

How the Pay is Determined

When it is known that after making due allowances for machine care, personal and trucking time, incentive, etc., a certain class of work should be put through at the rate of 100 pieces in so many minutes, say twenty for illustration purposes, what is more

*Statistician, Forest Products Engineering Co., Chicago.

logical than to pay the operator for twenty minutes per every hundred pieces put through. This is fair to both employee and employer alike. As an incentive allowance has been included, if the operator should turn the stock out at the rate of eighteen minutes per hundred pieces, he has still earned twenty minutes and would be paid for twenty minutes. In this way an incentive for close application and a basis for payment by performance covering all operations in a plant may be established that will result in increased productiveness for both men and machines as well as lower overhead costs per unit of production. After all this is nothing more than a practical application of common sense to woodworking practice.

What the Summer Furniture Markets Show

Not Many New Pieces Displayed at American Centres—Prices Have Been Steady with a Forecast of an Upward Movement in Fall —Buying This Year Exceptionally Heavy

In the matters of attendance, interest, display and orders booked, the midsummer furnishings markets at Grand Rapids, Mich., Chicago, Ill., and HighPoint, N. C., have been the best in several years. Manufacturers displaying their products at these exhibitions declase almost without excepton that they have received more real orders than two years ago when there seemed to be quite a demand for furniture. Over 2,500 buyers were registered at Grand Rapids and 4,000 at Chicago, while reports indicate that High Point had the largest attendance in the history of the Southern market. Buying held good from the first day, and many factories would accept orders for only sixty days' production, some of them selling out before the exhibitions closed.

Prices were very firm and showed practically no decline from those holding at the time of the winter markets. It was freely forecasted that prices would show an upward trend by fall, due to the steady increases in material prices. Perhaps it was this fact that led the buyers to buy heavily right from the start. It is said that some of the larger buyers were advising ordering in as large quantities as possible as they predicted good business prospects this fall with prices quite materially increased. At any rate the buying was the heaviest in two years and all the orders were considered bona fide.

As prices have held steady during the past six months there has been no reason for bringing out many new pieces and consequently the buyers at the midsummer markets were not confronted with many outstanding changes in design, at least, three-quarters of the goods exhibited being carried over from January.

No striking new finishes were displayed although it had been anticipated that new developments in this regard would be forthcoming. Very little polychrome or decorated furniture was exhibited, and in many cases manufacturers did not display any polished finishes but showed their lines in flat finish effects

Walnut was the favorite wood and easily outsold mahogany three to one. Gum oak, satinwood, birch and bird's eye maple seemed to be used in about the order indicated. The latter, especially for bedroom furniture, seems to be getting more popular, possibly because of a new rich brown finish that is being applied to it in place of the bleached finish for many years so prevalent. Some makers are also using curly birch with a finish somewhat approximately the appearance of light walnut. Oak in the grey finish has met with some demand. At High Point an exhibit of a Tennessee red cedar bedroom suite attracted considerable attention, and many buyers, in placing trial orders, ventured the belief that this wood will become more popular in the future. Its application in the past has been largely limited to chests and drawer linings. A tendency towards the use of solid woods was observed, many firms which has been using gum legs and posts changing to solid woods.

As far as styles are concerned, there has been no outstanding change in the last six months. English and French influences seem to predominate.

Reading lamps and floor lamps of all descriptions were shown at the markets and were even more handsome than designs previously exhibited. Distinctive shades in a wide range of the colors added to the effectiveness of the display.

Evansville, Ind., will be the location of the next furniture market, September 11-16, being the dates. It is anticipated that the Evansville manufacturers will bring out new designs at attractive prices. The New York display will follow on October 16-18 with the Jamestown exhibition in November.

U. S. Furniture Manufacturers Want Change in Grading Rules

The National Council of Furniture Associations has requested that the National Hardwood Lumber Association abandon its efforts to formulate and establish a hardwood sales code, and devote its energies exclusively to co-operating with the ultimate purchasers of lumber to see that the national hardwood grading rules are developed to as near perfection as it is possible. In addition the Council has suggested changes in the grading rules.

In a bulletin to its members, which repeats the original statement held on July 21 in Chicago, asking that the code efforts be abandoned, the Council announces that arrangements are being made for a conference between the Council's Committee on Lumber and the Grading Rules Committee of the National Hardwood Association, to consider the proposed changes. The changes which the Council proposes are as follows:

Eliminate—Grade "Selects."

Eliminate—Grade Quartered Red Gum—Sap no defect" and substitute for same—grade Quartered Sap Gum.

Eliminate—The "4 per cent" clause.

Insert—Season checks should be considered serious defects.

Change—No. 1 Common to read "'4' and over wide."

Change—Rules to read "All lumber should be graded from the poor side of the board."

How to Level and Tension Large Band Saws

Directions for Testing and Correcting the Tension and Straightness and so Prolonging the Life and Usefulness of Band Saws—Case Hardening to be Carefully Guarded Against

The life of a band saw depends very largely on the way it is handled, particularly when it is new and before it has been perfectly adapted to the wheels on which it is run. Many operators expect a new saw to do more work than one which has been perfectly adapted and adjusted to the wheels and the alignment of the mill. This is a mistake for their are peculiarities about every mill, and until a new saw is adjusted to

Fig. 1—Showing lump or "fast" spot

the face of the wheels, their aligning or tilt, the speed and feed, they cannot be expected to give as good results as the saw which has been properly adjusted in relation to these factors.

There is a certain quality about a new band saw which we can best describe by calling it "surplus" elasticity, and until this quality is brought down to its proper bearing by the judicious use of the hammer and saw stretcher in connection with the first "runs" of the saw, it will not be at its best. All experienced filers and millmen know that excessive speed, too much tension, uneven tension, case-hardening or glazing from the emery wheel, gum adhering to face of wheels, crystallization from too heavy hammering, cuts on the surface of the saw from sharp-faced hammers, vibration of either machine or saw, sharp angles in the gullets, imperfectly-adjusted guides, backs of saws too long or too short and excessively cross-aligned to make them "track," insufficient throat room and hook, and crowding the saw against the guard wheel, will cause it to crack. These are all well-known causes of breakage, yet notwithstanding the knowledge that all band saws are more or less subject to these conditions, too often the cause of fracture is attributed to the quality of the steel or over-hardness.

Many operators of band saws ask advice as to the best manner to fit, tension and operate the saws to attain the best results and to get the most wear out of them. It is with the idea of furnishing some practical information along this line that this article is published, based on practical data submitted by Henry Disston & Sons, Inc., the well-known saw makers. The instructions which follow cover the levelling and tensioning of band saws, properties that are extremely important if their life is to be prolonged and the best quality workmanship obtained from them.

Large band saws, when running idle, should travel in a true plane, with the cutting-edge projecting over the edge of the wheels about the full length or depth of the teeth. This can be accomplished only by true alignment of shafts, proper tilt of wheels, and as regards the saws, accurately made brazes, correct tension, right amount of hook to the teeth for the kind of lumber to be cut, properly swaged and fitted. Assuming the foregoing adjustments have been made, the saws will travel in a true plane and hold their position on the wheels without any lateral motion either in or out of the cut.

Tension means strain and is obtained by stretching

Fig. 2—"Drop" in blade fits tension gauge

the blade between the edges with the tensioning rolls or hammer. If a hammer is used, one with a round face is preferred. The saw must be made flat or level before tensioning. Examine carefully with a straight-edge for lumps across and lengthwise, trace lumps to their full extent and remove by striking with a long or a cross-face hammer as the direction of the lump may require. Be careful not to cut the lump into several small ones by spreading the blows. Hammer lightly and closely—the nearer the blows come together the better. Examine frequently with the straight-edge. Reverse the saw occasionally for inspection, as a beginner is apt to hammer more than is necessary, thus dishing the blade. A little practice

and close attention will soon enable the learner to flatten or level the saws correctly. ,

Proper Amount of Tension

The next operation after levelling the saw is to examine for tension by using a tension gauge. The proper amount of tension varies according to the feed of the mill and crown of the wheel, but under no circumstances do we think it judicious from any point of view to put in so much tension that the saw will not lie flat from its own weight on the levelling table.

Raise the saw, as shown in Fig. 1, holding the tension gauge at right angles to the blade. Mark all fast spots with a crayon, tracing from the beginning and end of each spot. The fast spots are indicated where the centre of the blade shows as a lump under the tension gauge as in Fig. 1.

Roll or hammer between marks until the saw shows under the tension gauge as seen in Fig. 2. Test after each line through the rolls. Roll from the centre of the blade to within about three-quarter of an inch of the edge. If the hammer is used for

Fig. 3—Too much "drop" under tension gauge

tensioning, the blows must be applied on both sides of the blade to prevent dishing. Do not tension on a cast iron block, which is to be used only when lumps are being removed. A hard-faced anvil should always be part of the equipment.

Examine with a straight-edge each time a roll or hammer is used for tensioning and remove any lumps which may have developed. If too much drop shows under the tension gauge, as shown in Fig. 3, roll or hammer on both edges until the drop properly fits the gauge on both sides of the saw.

Examine the back-edge of the saw with a back gauge (See Fig. 4). Mark the extent of the hollow on the back of the saw, if there be one, and roll or hammer from mark to mark. Begin at the centre of the saw and work to the back edge by rolling parallel with the saw. Repeat, if necessary, until the back is stretched to fit the gauge. If the back should be full or lumpy, follow the same course, working from the centre of the blade towards the tooth-edge.

Examine the saw with a straight-edge for lumps and with a tension gauge for irregular tension. Make corrections as the work progresses. When ready for the wheels, the saw should lie flat on the levelling block and fit the tension gauge on both sides when curved and tested as in Fig. 2.

Fig. 5 shows the test for tension on the up bend or outside curve with a short straight-edge. If the saw is correctly tensioned an almost perfect curve will show under the straight-edge between both edges of the saw. If it shows flat, trace its extent and stretch

Fig. 4—Testing the back of the saw

it with a roll or hammer until it shows an even curve.

Accurate Fitting

After the saw has been properly tensioned it should be accurately fitted. The swaging and fitting of the teeth are practically the same as in a full swaged circular saw. The swaging is side dressed or shaped to a uniform width with an under and back cut in order to leave the extreme point of tooth a trifle wider than the rest of the tooth. The full amount of swage when side dressed should never exceed No. 8 gauge in a 14 gauge saw and for hard timber may be even less. It is advisable to run with as little swage as practicable. The tensile strain on

Fig. 5—Testing tension on the up bend

the saw, the power required, and the waste of lumber in the kerf depend to a certain extent on the degree of swaging.

It is also necessary to re-sharpen band saws frequently. Many saws are ruined because they are run after they have become dull. No band saw should be run longer than two and a half hours on one sharpening.

Well tensioned and well fitted band saws, when

properly handled, will stand the maximum feed and manufacture good lumber. But, after the corners of the saws become worn or dull the saws will dodge or leave the line, which has the effect of destroying the tension and fracturing the saws.

Sharpening Band Saws

In sharpening use a medium soft emery wheel and do not crowd it on its work as this would result in case-hardening the gullets. Cracks are liable to start from any one of these case-hardened spots.

Do not give the teeth sharp gullets. This concentrates the bend of the saw too much at one point as it runs over the wheels. Use a round gullet, as large as practicable, with no sharp corners or abrupt angles.

Never let the back edge of the saw come in contact with the back guard wheel or any other hard

Tension gauge

surface, as case-hardening is bound to ensue from which cracks will surely result. Should the saw be accidentally forced against the guard and case-hardened, remove the glaze at once by holding a piece of soft emery wheel against the back edge while the saw is running slowly. Do not take for granted that the back edge of the saw has not been in contact with the guard wheel. Try a file on the edge of the saw frequently, as only one revolution with the back edge against the guard is necessary to bring about case-hardening. This is done so quickly that it often happens without the knowledge of the operator.

The majority of the large mills are now using the roller or stretching machine for putting in the tension. The desired effect can be attained in a shorter time and with less injury to the saw than if the tension were put in by a hammer. It is necessary, however, to use the hammer for finishing and regulating, after the use of the stretcher.

C. S. Fields Married

We are sure that there are scores of our readers who will congratulate Mr. C. S. Fields, the Canadian representative of the National Dry Kiln Co., on his recent marriage. The young lady involved was formerly Miss Eva Wilson of Toronto. The couple will reside at 7 Jerome Ave., Toronto.

At a meeting of the Hardwood Manufacturers' Institute held in Memphis, Tennessee, Saturday July 29th, S. F. D. Meffley was appointed assistant secretary of the Institute in direct charge of all membership, publicity, advertising, educational and trade extension work. Every manufacturer of hardwoods in the country will be invited to become members of the Institute; all fabricators of lumber will be invited to participate in the co-operative plan in a friendly and earnest endeavor to carry out the standardization program, so that the decreased cost in production, distribution and fabrication may be reflected to the ultimate consumer of the product.

Asphalt and Pitch Paints Efficient Moisture-Proofing Agents for Wood

That some asphalt and pitch paints because of their ease of application and moisture-resistant quality are nearly as efficient as the aluminum-leaf finish now used on airplane propellers, is the evidence obtained by the United States Forest Service in a series of tests which it conducted during the past year in co-operation with the Navy Department at the Forest Products Laboratory, Madison, Wisconsin.

The Navy Department is seeking a moisture-resistant coating of easy application with which to coat seaplanes made of many small wooden parts glued together. On account of the variations in stress resulting from the severe extremes of moisture which a seaplane encounters, it is important to protect the wood with a coating through which the moisture will not penetrate. Otherwise the wood joints may be weakened. Few of the many coating materials already tested have given adequate protection even though several coats were applied. The aluminum-leaf used on airplane propellers is the best moisture-proof coating known, but it is not suitable to apply to the many small and intricate parts which make up the wings and hulls of flying boats.

Some of the asphalt and pitch paints tested were very moisture-resistant, and others were ineffective. Further investigation is to be made to determine the relative value of the different kinds available, and the Forest Products Laboratory, invites the industries concerned to contribute information, suggestions, and samples of paint for use in this study.

When other colors than black are desired, asphalt and pitch paints have been found objectionable, since it is difficult to cover them with paints of a lighter color. It is hoped that this defect can be overcome by developing different methods of applying the final coating.

England Needs Oak Veneers and Plywood

The London journal "Timber," in its plywood section of the July 1 issue made the following interesting comment on the need in Great Britian of oak veneers and plywood:

"Whilst on the subject of veneers, we can still comment on the shortage of figured oak veneers and figured oak plywood, for we understand that the trade is in a position to soak up many times the quantities that are at present arriving. Only a very few bundles of figured oak plywood have been landed for some months, and these have been very quickly absorbed, and the trade have been perfectly content to pay what we consider high prices. Again the question of supply and demand predominates, and this question is becoming more and more apparent every day, especially on such articles as figured oak. What a harvest could be reaped by any supplier who could place on the market to-day a good supply of well-manufactured figured oak plywood. The same thing applies to ash. Although there are a fair number of bundles to be obtained, there is still a shortage of "really good stuff," and with the demand remaining strong, the prices are, and will be for some time, kept at their present level, even if they do not increase. We feel that good ash plywood will be called for by the users to a great degree in the very near future."

British Columbia Woods Make Handsome Trim

Demonstration Suite of Rooms Effectively Displays the Advantages of Western Woods—Exhibit of Great Service to Woodworkers by Interesting the Public in Good Trim Effects

By L. L. Brown*

The beauty and utility of British Columbia woods are being demonstrated in an effective way in the form of a permanent exhibit of a suite of rooms, comprising a living room and a dining room with outside walls and roof complete, which have been built on the ground floor space of the British Columbia Lumber Commissioner's office at 51 Yonge Street, Toronto. This exhibit represents a co-operative effort by the British Columbia provincial government and the lumber and shingle interests of the province, and is not only of interest to architects and builders but also to the manufacturers of wood trim and of lumber products generally.

The whole is a studied attempt to show the people of Eastern Canada the full beauty of British Columbia woods when used in the construction of Canadian homes, for it is felt that the sturdy woods of Canada provide both beauty and strength required for even the most palatial abode.

Heretofore, the intending builder has had to visualize from small samples just how a completed room would appear in these woods, but now even the layman may see at a glance just how beautiful his home may be made by the use of Canadian grown woods. And when he considers that these effects are obtained at about half the cost of using imported hardwoods, he will at once see the advisability of embodying them in his future home. Already a great deal of favorable comment and even astonishment has been expressed by architects, contractors and homebuilders upon the natural beauty of the woods used and their adaptability for even the finest class of homes.

*British Columbia Lumber Commissioner, Toronto.

This illustration shows the attractiveness of Douglas fir panelling

The living room, which is about 13 ft. by 16 ft., is panelled in British Columbia Douglas fir. Flat grain three-ply wood is used in the panels proper and edge grained wood is used for styles and rails and general trim. At one end is a large inviting brick fireplace. The ceiling is beamed and with solid Douglas fir beams with three-ply cottonwood panels between. The room is finished in artistic subdued tones which bring out the natural beauty of the wood to splendid effect.

Passing through an arch, one enters the dining room which is about 12 ft. by 16 ft. 6 in. This room is complete in every way with built-in china cabinets, small bay windows, brick and stone fireplace and French doors. The walls are panelled in Western hemlock; the panels proper being of flat grained solid pieces with edge grained style, rails and trim.

A great deal of surprise concerning this wood is expressed by architects and homebuilders for they have been apt to confuse Western hemlock with the Eastern variety of the same name, which is only used for the roughest work. But a study of this beautiful room shows that Western hemlock has little in common with the Eastern variety for it is a high grade wood, very suitable for interior trim. It is light, straight grained, easily worked and takes a beautiful finish.

British Columbia red cedar beams

are used for the ceiling of the dining room with admirable effect. It shows that red cedar beamed effects are suitable not only for work such as the much admired Music Room at Hart House, University of Toronto, but that this wood is also effective in beautifying the rooms of moderately priced homes. The ceiling is panelled with three-ply cottonwood veneer in a smooth, satin, maple finish. Edge grain Western larch is used for flooring in this room.

Cottonwood panels have been little used in the East as yet for panelling, but their cheapness, quickness of application and ease in finishing to any desired effect will soon make them very popular for panelling halls, dens and dining rooms.

The outer walls of this "house within a house" as it has been called, shows the beautiful effect obtained by the use of British Columbia red cedar shingles. The twenty-four inch Royal grade was used. These shingles have substantial butts one half inch in thickness. They were first treated by being dipped in a Dixie white paint and then laid on the wall with a ten and one half inch exposure to the weather. Afterwards, they were given two coats of Dixie white which gives a splendid effect.

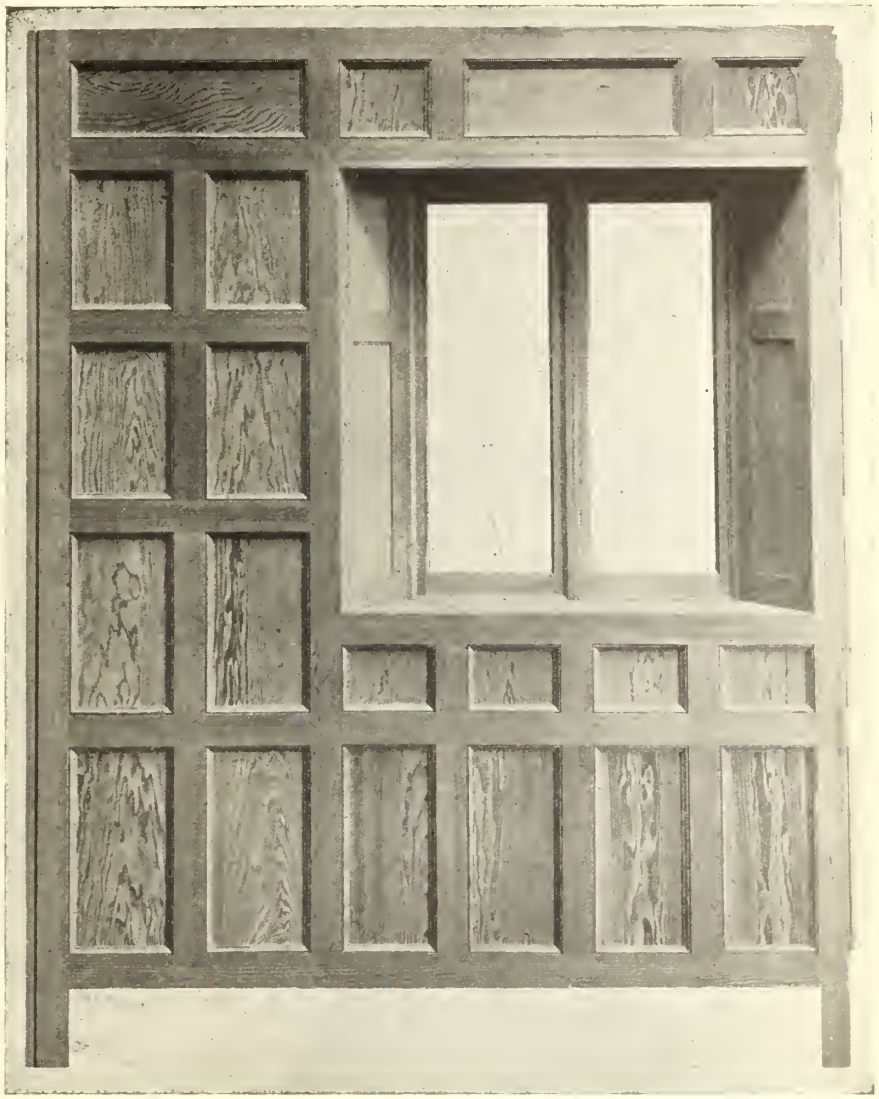
The roof portion is of XXXXX B. C. red cedar shingles with some of them bent to give a thatched roof effect. They were laid with an irregular wavy exposure to the weather. Before laying they were Creo-Dipped in shades of green, red and brown. This gives a pleasing effect when they are laid in alternate colors. As this is one of the first examples of thatched roof effects in shingles to appear in Toronto, it is causing a great deal of interest and favorable comment.

Hot dipped, zinc-coated cut nails were used throughout for laying the shingles. This was done with the hope of influencing architects, contractors and homebuilders to use first class shingle nails. Too often it has been found that the ordinary wire shingle nail does not give a service nearly equal to the life of the shingles. In this connection it may be noted that already a large number of progressive retail lumbermen are carrying a zinc-coated shingle nail which gives excellent results at a very small additional cost, indeed, so small as to be negligible when the additional life of the roof is considered.

Western white pine was used for the exterior finish and proved itself highly adaptable to the somewhat delicate detail required for trim around the main entrance door.

The rooms are completely furnished with Canadian made furniture and all lighting fixtures are installed just as they might be in any home of good taste.

The cumulative effect of the whole has resulted in an exhibit which will have a great educational effect on Ontario homebuilders in the use of good Canadian grown woods for Canadian homes.



Exterior window and panelling in Western hemlock

It is hoped that this exibit will be of great service to woodworkers and manufacturers of interior trim by showing the powerful effect of such a finished exhibit as an advertising and selling force. The propaganda of the manufacturers of substitutes must in time have a serious effect on the lumber and mill business in general unless counteracted, and it would seem that there is no better way to sell wood products than by showing the people what can be done with wood. Finished rooms or suites as that now completed for the British Columbia forest industries comprise a splendid way of convincing even the most exacting homebuilder just what can be done with native grown lumber.

Grading of B. C. Woods

Another exhibit now under way at the same address as the exhibit just described is a "Grading Exhibit of British Columbia Woods." At the present time very few architects or engineers clearly specify lumber according to actual grades and many are the misunderstandings and disputes which arise from this

incomplete method of specifying. In order to overcome this and to show the actual grading of British Columbia woods, it is proposed to place on exhibit several pieces of each grade manufactured. Different sizes will be shown framed in convenient display racks. All pieces will be about ten feet in length, so that an excellent idea of grades can be obtained by the architect or engineer before specifying.

The same will apply to shingles, for market extension men have found that there is room for considerable educational work amongst architects in the right specifying of shingles. Few of them are aware that there are other grades than XX and XXX red cedar shingles and they are always astonished and

Built-in china cabinet and panelling in Western hemlock

pleased when shown XXXXX, Perfections and Royals as manufactured in British Columbia. In this exhibit all grades will be shown which will be of great help to architects and homebuilders in solving the important problem of a durable roof.

The old time, easy methods of obtaining orders for wood trim have had to bow to inevitable progress, and clean cut selling methods, backed by service, are now recognized as necessary by all millmen. In this connection display of woods embodied in the structural and finished portions of life-size rooms should prove weighty factors in the distribution of good wood trim. The keen interest already shown in the pioneer built-in exhibit of the British Columbia forestry service bears this out to the letter. Just as architects and homebuilders have always studied the finished effect of the past domestic architecture of all ages in search of the beautiful for their own creations, even so will they study with satisfaction the finished design as shown in room and suite exhibits, When they are interested to the point of desire they are more than half sold.

Standardization of Sash and Door Stock

The attitude of sash and door manufacturers of the United States toward the lumber standardization movement is expressed in a formal statement issued by the Wholesale Sash and Door Association and submitted at the meeting of the National Lumber Manufacturers Association held on July 20-22 in Chicago to discuss standardization matters. The report reads as follows:

"First, we are in sympathy with the grading of all lumber under national supervision and any other constructive work which will make the activities of the scalawag more difficult.

"Second we are concerned especially with the thickness and grades of factory plank, known better as shop lumber, in the grades of Nos. 1, 2 and 3 shop and third clear. We would be opposed to any change in the grading rules applicable to these four grades. We also would oppose strenuously and wish to impress upon you the mighty seriousness of a change in the standard thicknesses now in effect. The 4/4 shop standard thickness is 13/16 from some territories and 25/32 from others. This we should like to see standardized at 13/16, thereby permitting the furnishing of mouldings and cupboard doors ¾-inch thick to better advantage than now being done when there is but only 1/32 on which to work. The standard thickness of 5/4, 6/4 and 8/4 lumber should, in our opinion, be left where it is at 1-5/32, 1-13/32 and 1-25/32 respectively.

"Third, we have no fault to find with the present standard thicknesses of hardwood lumber or 4/4 yellow pine and fir. We should, however, like to see 5/4, 6/4 and 8/4 yellow pine finish furnished surfaced two sides to 1-5/32, 1-13/32 1-25/32 respectively. Under the present standard thicknesses, we are unable to furnish 1⅛-inch cupboard doors or 1⅜-inch or 1¾-inch standard doors without having lumber cut especially for the purpose. In manufacturing 1⅛-inch doors and 1⅜-inch doors, it is necessary to use 1¼ and 2-inch lumber respectively. We should like to see the rules modified so that yellow pine finish would be available to sash and door manufacturers in the same thicknesses as the western pine, thereby permitting a greater use of this particular wood. These remarks regarding yellow pine apply perhaps to a greater extent to fir."

U. S. Toy Manufactures Meet

The Toy Manufacturers of the U. S. A. held their midsummer meeting at Manchester, N. H., on July 20 with an attendance of nearly 100 manufacturers of toys from all parts of the country. A review of conditions indicated a bright outlook for the industry, although some fears were expressed that German competition would affect the American trade because of the low cost and in spite of the high tariff.

Public Confidence in the Furniture Industry

The Adoption of Standard Furniture Designations Will Help to Eliminate Unscrupulous Dealings and Unfair Competition—A New Set of Names Drawn Up by Associated Advertising Clubs, Broadcasted to Retailers

Fifteen thousand furniture retailers have recently received from the Retail Furniture Association of the United States a circular describing the standard furniture names recommended by the National Vigilance Committee of the Associated Advertising Clubs of the World. The definitions embodied in this circular are those under which this committee believe it ethical for the retailers to sell furniture.

Accurate and uniform names for the various classes of furniture have long been desired by far-sighted men in the industry. There has been a need for them, not that there has been an unusual amount of confidence-destroying and unfair practice in the furniture business, but there has been enough to make it important that the public be given a dependable guide to furniture descriptions, and that legitimate merchants be provided with a standard to which they can rally—a basis of confidence-building practice on which better business may be permanently built.

In the formulation of the standard furniture names, consumers, retailers and manufacturers have been consulted and the authoritative character of the recommendations gains by the fact that they are based substantially on terms proposed by the National Council of Furniture Associations for the use of manufacturers. The recommendations are as follows:—

SOLID—Furniture designated as solid mahogany or walnut shall have all exposed surfaces of solid wood of the kind designated.

MAHOGANY OR WALNUT—Furniture designated as mahogany or walnut shall have all exposed surfaces (both solid parts and plywood) of the kind of wood designated.

COMBINATION—Furniture designated as combination mahogany or walnut shall have all exposed surfaces of mahogany or walnut (solid or plywood) in combination with gum, birch, or other suitable wood.

The kinds of woods used in combination with mahogany or walnut should be named, for example: "Combination mahogany and birch," "Combination walnut and gum."

IMITATION—Furniture designated as imitation mahogany or walnut shall be that with exposed surfaces of other woods colored to imitate mahogany or walnut.

Where other woods are used, the name of this wood is to be substituted for that of mahogany or walnut in the definitions.

The term "exposed surfaces" shall mean those parts of a piece of furniture which are exposed to view when the piece is placed in the generally accepted position for use in the home.

Manufacturers of furniture are much interested in any movement that attempts to standardize the names under which their products are sold. All too often the terms used have been the basis for promoting misunderstanding between a store and its customers, or have been a harmful instrument of unfair competition. They have given the unscrupulous dealer undue advantage over the honorable retailer, and, in many cases, have undermined public confidence in the furniture business.

Unscrupulous Retailing

We do not believe that among honest and scrupulous furniture retailers there has been any attempt to wilfully deceive the public but there have been instances where some have designated on their invoices a combination suite or an imitation suite as "mahogany" or as "walnut," largely because of custom. Some retailers, too, attempt to obtain a greater profit than is warranted by the cost of the suite or article, by selling it as "solid mahogany" or solid walnut," and, if caught, have tried to justify themselves by saying "We did not know. It was billed to us as mahogany." Thus they try to pass off the fraud on the manufacturer. Of course the manufacturer may not claim responsibility for what the retailer tells his customers. Some, indeed, claim that they are not interested in how or by what means their products are retailed. However, those manufacturers who wish to improve the status of the industry and create public confidence in furniture and the makers of furniture, have an interest in seeing that the public's faith is not undermined. Any attempt, therefore, to standardize furniture names and induce retailers to employ them in their sales talk, should meet with the hearty approval of the manufacturers and be enthusiastically encouraged by them.

When retailers advertise their wares they should be careful to use the proper standard term that sufficiently designates the type of furniture in question. No juggling of expressions or laxity in description should be permitted. In fact, it was from the advertising viewpoint that the National Vigilance Committee of the Associated Advertising Clubs took up the matter of standard furniture names. Their object is to promote truth in advertising—a policy that deserves encouragement on the part of every manufacturer, jobber or retailer. In the furniture field the manufacturer can lend his assistance by seeing to it that his own advertising is quite clear of any misuse of descriptive language.

The Manufacturers' Part

We have seen it urged that manufacturers should print on the front page of their catalogues a heading somewhat as follows:—"We have adopted for our own use the trade names printed below. This is done that there may be no misunderstanding as to the construction of the furniture that we ship to our customers." Then follows the list of terms as printed in a previous paragraph. This is just one scheme by which the manufacturers can indicate to their customers that they are in accord with truthful descriptions of their products and are not willing to condone inadequate descriptions or deliberate falsehoods.

The publicity that is being given to the standard furniture names through the distribution of explanatory circulars to 15,000 retailers is bound to have an improving effect on retailing methods. It must not be thought, however, that in the marketing of furniture, there is any great degree of unscrupulousness; in fact we are confident that the great majority of furniture merchants are not taking any undue advantage of their clientele, thanks in no small degree to the high quality of the furniture turned out by a vast percentage of the factories throughout the country.

How to Handsomely Increase Your Profits

Make Use of the Vastly Improved Equipment that is Offered the Woodworker To-day—Modern Machines Show Remarkable Developments that Produce Better Work at Lower Cost—The Value of Bench Outfits

By D. L. Clarke

To those who have followed in a more or less casual manner, the changes which have been brought about in the design and development of woodworking equipment during recent years, the refinements and improvements which have actually been made will prove little short of a revelation. It is not enough to know that such and such a machine is on the market or that so and so is bringing out some new equipment. To keep really abreast of the times it is necessary to make a detailed study of all new developments in this particular field and learn in detail just where and how the various improvements have been made.

While this naturally will require a certain amount of time and effort, yet it will be time well spent. Not only that but to the woodworker who is progressive and who is entensely interested in his work such a practice should be a real pleasure, a sort of pleasant pastime, as it were.

Without attempting a detailed analysis of the design and application of modern woodworking tools it might be of interest to touch lightly on some of the changes which are found. The development and improvement which has occurred in this line may be divided, broadly, into four divisions.

First: Improvements tending toward increased output and better work.

Second: Equipment for the automatic quantity reproduction of parts or articles that were formerly produced by hand operations.

Third: Greater attention to design construction and workmanship.

Fourth: Refinements that tend to facilitate operation, lighten the work of the operator and also tend toward greater comfort for the operator.

How Output Has Been Increased

Enlarging on these divisions, briefly, the trend toward increased output and smoother, better work has been brought about largely by faster feed speeds, made possible through increased cutter head speeds, more cutters per head, grinding and jointing attachments and greater weight and rigidity to the machines, and also through the perfection of double end equipment such as tenoners, cut-off and mitre saws and further with multiple spindle mortising and boring equipment. Better quality work leads in turn to increased output in other directions for improving the quality of the output of the planer and sticker, means that less sanding is required and up goes the output of the sanding department. Similarly the increased accuracy of the work of the double-end machines eliminates much of the fitting so often found necessary and thus facilitates the movement of work through the assembling department and so on down through the whole list of woodworking operations.

In the second division would be found such machines as automatic turning lathes, leg-forming equipment and special automatic sanding machines such as for turnings and mouldings. This outline would hardly be complete if some reference were not made to automatic screw driving and portable screw-driving and boring equipment. Here again hand operations are eliminated and productions raised.

Better Designed Machines

Under the third heading some startling innovations have been made. Whereas, formerly little attention was paid to the manufacture of woodworking machinery, to-day the same care and workmanship is exercised that goes into the better class metal-working equipment. This has resulted in machines that are pleasing to the eye, particularly to those who appreciate good workmanship, but more to the point is the fact that such machines work with a degree of precision and accuracy that was lacking in most of the equipment made a few years ago. In design, greater attention is being paid to rigidity so as to eliminate as much vibration as possible. Not only is vibration a hindrance to the production of smooth work but it shortens the life of the equipment to an appreciable extent. For this reason solid, well-built equipment can be depended upon for better work and to give longer service and as a result is cheaper in the long run.

The fourth division was given as, "refinements that tend to facilitate operations, lighten the work of the operator and that also tends toward increased comfort for the operator." This has to do with the placing of operating levers, provision for changing adjustments, shifting belts, etc. An attempt is made to have everything right at hand and in a convenient position so that excessive stooping and awkward positions may be avoided. In some cases power adjustments have replaced hand levers and wheels. All this facilitates the operation of the machine and tends to raise production.

The Operator's Comfort

The comfort of the operator is considered by the placing of the operating and adjustment controls and also by the provision made for carrying away the dust and shavings. This latter feature is receiving more and more attention with each passing day. Some of the newer belt sanders, for instance, have one end completely hooded in with a suitable connection to the shaving exhaust system. While there may not be anything new in this idea, the thoroughness of its application is unusual and marks a new step in this direction. The same applies to the attention being given to the collection of dust and shavings on other equipment, even on such machines as jig saws and bandsaws.

Other phases of woodworking machine development might be touched on if space permitted, such as the application of ball-bearings, which is becoming quite general, and the economies in power, repairs and lost time thus effected, also the development of light portable machines of various types. The idea of replacing hand work by providing light equipment which may be taken right to the bench, appears to be only in its infancy. The idea is basic and

offers a chance for real economies in assembling and hand operations.

Summing it all up, the woodworker is to-day offered many opportunities for improving the quality of his output, increasing production and reducing costs through the purchase and operation of modern types of equipment. At first glance the cost of making such changes may seem high, but the results which would be achieved would more than justify the expenditure. This was put very aptly by a writer in the June "Canadian Woodworker," who stated that the only basis upon which to judge the value of any machine is not the initial price, but its productiveness and the quality of its output. On this basis, there should be a rush for new and improved machines, for an investment in modern tools will be returned in a few months and a handsome profit will result for years afterward.

What is Wrong with these Cost Figures?

Wide Variations in Certain Factors Indicate the Need for Improvement in the Method of Taking Off Quantities and Estimating Costs—What Effect Has Delivery on the Cost?

The cost study for this month involves three doors in whitewood, a problem that has been submitted to us by a mill operator who had this order on his books a short while ago. He was very interested in determining just how his figures compared with estimates of other millmen; consequently we asked in our June issue for cost estimates on this order. The half dozen or so figures tabulated below are the result, and they are seen to afford an interesting comparison and teach several important lessons.

In this instance there is not the same variation in the total cost that has been apparent in some of our other cost studies. The range is from $63.44 to $69.54, which might seem to indicate that the basis of cost is about the same for all the estimators. An investigation, however, of the various factors involved in the total cost shows wide discrepancies and indicates that there is still need for the adoption of more reliable costing methods.

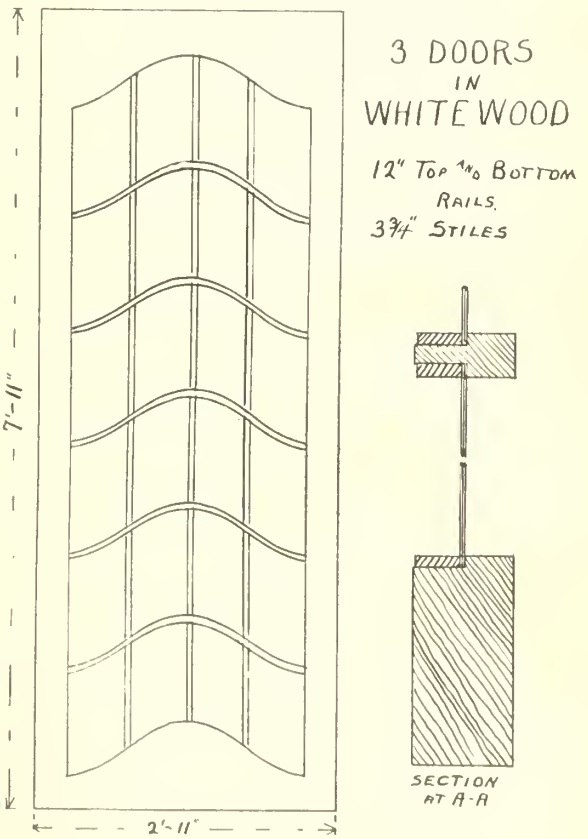
Estimate of Cost of Special Door Order

No.	Material	Waste	Bench hrs.	Rate	Machine hrs.	Rate	Commercial Burden	Total
1	$17.50	10%	9	$ .85	21	$1.00	10 %	$63.44
2	18.05	20%	19	1.00	8	1.50	20 %	64.62
3	13.56	20%	15	.85	10½	1.07	20 %	65.09
4	12.25	10%	12	.85	25	1.10	12½%	65.65
5	20.05	15%	24	.90	6	1.50	15 %	67.22
6	14.35	10%	3	.90	10	2.00	25 %	67.49
7	18.75	25%	16½	1.00	7½	1.25	15 %	69.54

Who is Right?

The first factor is the material, and here there is considerable variation in the figures—about 60%. Possibly this is due to the fact that as one man told us, 20% of the planing mill men do not know the correct price of whitewood. The figures we have received certainly show considerable discrepancy in the quoted price of whitewood, but furthermore there appears to be no uniformity in the estimates of the amount of material required. One millman figures as low as 63 feet and another as high as 140 feet. It is obvious that some of the estimators need some lessons in the taking off of quantities.

The labor hours, both bench and machine, show some startling discrepancies, the bench hours varying from 3 to 24, and the machine hours from 6 to 21.



The subject of cost study for this issue

Again, it is obvious that there is no justification for such variation in the estimates. Making all due allowance for the differences in the equipment and method of handling this order on the part of individual manufacturers, there is no reasonable excuse for the discrepancy that is indicated by the figures—a case again where millmen are not sufficiently well acquainted with the costs on previous work to be able to make an estimate with reasonable assurance of hitting the mark.

The importance of waste in an estimate of this character is emphasized in a letter which accompanied one of the cost figures which was submitted to us. This stated: "Waste is in a measure still the un

known quantity. This will be governed by the grade of lumber bought or available, and the availability of opportunities to use what would otherwise be waste. Hence we think the great difference in either estimates or guesses." The word "guesses" in this comment about expresses the true situation as far as many of the estimates in these cost studies are concerned. However, it is just to help in eliminating such guesswork that the "Canadian Woodworker" has carried out the policy of a monthly cost study. It is undoubtedly having a beneficial effect, if we are to judge by letteres of commendation that continually reach us. Several letters this month have stated that the mills concerned appreciate the good work that is being done through the medium of these cost studies, and urge us to continue our efforts toward putting the millwork business on a better footing as far as its costs are concerned.

The Effect of Service

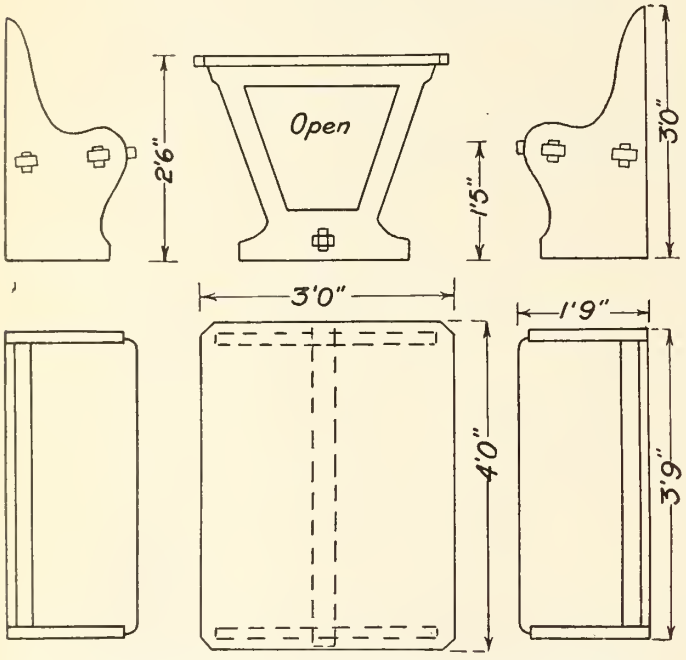
In connection with these cost studies many important points come to light. One such point is emphasized in one letter in which the writer, a prominent Ontario manufacturer of stock lines, comments thus:—"At some future time we hope you will take up the question of 'what effect has prompt delivery or service in connection with such matters-' Very often it has a very direct bearing on costs as well as on the satisfaction of the customer. Buyers will shop around for a month or so and then expect delivery on a few days' notice. Evidently they have not yet learned that a factory should be booked ahead and that other people require orders filled. This is and has been a long-standing trouble." Will our readers not take up this question and write their opinions for publication in the "Canadian Woodworker?" An important point is brought up in the comment quoted above and there is nothing like a frank expression of opinion to clear the difficulty up.

It would be interesting to compare the figures listed with those submitted by the firm that actually handled this order. The doors which they made were 1¾ inches thick while those on which this cost study is based, are 1⅜ inches. However, there would be little difference in the price. The following is the actual cost:—

Material, 140 feet whitewood at 15 cents ..	$21.00
20% waste	4.20
7 machine hours at $1.10	7.70
66 bench hours at .85	56.10
Total cost	$89.00

For the September issue we have taken a breakfast nook set, including a table and a pair of seats, such as are used in breakfast rooms in many modern houses. This is, perhaps, a little simpler order than we have been running in the series of late, but it is in response to an appeal from several millmen who ask for something that is more frequently handled by the average planing mill. We hope that this will bring ont an unusually large number of replies. Please submit your idea of the cost at the earliest opportunity.

What Can You Make this Job For?



Send in your estimate of cost of this breakfast nook set and compare it with the other fellow's. The figures will appear in the September issue

National Lumber Manufacturers' Association Discuss Standardization

What is regarded as a step forward in the standardization of lumber sizes among lumber manufacturers was developed at the second general conference, held under the auspices of the National Lumber Manufacturers' Association, at the Congress Hotel, Chicago, on July 20, 21 and 22. Prior to the series of conference that were called for Chicago, there had been held during the previous week at the Forest Products Laboratory at Madison, Wis., a conference of experts which formulated a plan of procedure, or rather a set of tentative rules for the standardization and grading of softwoods.

At the Chicago meeting, an addition covering hardwoods was made to the Madison report as follows:

It is recommended that:

(1) A complete engineering survey be made to determine if grades can not be constructed to more closely meet present consuming requirements.

(2) The present hardwood grades be divided into the three general classes recommended by the Washington conference; and it is suggested that this division of the present grades be made as follows: A—To include those grades which are practically clear or are determined by a limited number of enumerated defects of minor character; B—To include those grades which are determined by clear or clear face cuttings; C—To include those grades which are intended for uses where reasonable strength is required, and where certain percentage of sound cuttings is the determining factor.

(3) In the event a revision or reconstruction of grade specifications is found to be necessary from the survey that is recommended, the same general division can apply to the revised or reconstructed grades.

However, as the conference was not empowered to adopt or reject anything, but could merely receive and consider opinions on matters relating to the standardization program, no action was taken on these recommendations.

Edison has said that the day will come when no human hand will touch a piece of work that can be done by machinery.

Up to a Standard, Yet Down to a Price

Designing a Crate for a Special Purpose, Where Strength was Essential but Price was also an Important Factor—The Three-Way Notched Design Showed a High Degree of Rigidity and Saved Labor in Assembling

By J. R. Watkins

The laboratory engineers are often called upon to design a low-priced box or crate, and although they are not always requested to produce a stronger box at less cost than had been used, it is their desire to combine these essentials. Nor does their work end with the box or crate design. Whenever possible, they make a study of the box assembling, and this often calls for designs of nailing forms to expedite the nailing up and packing.

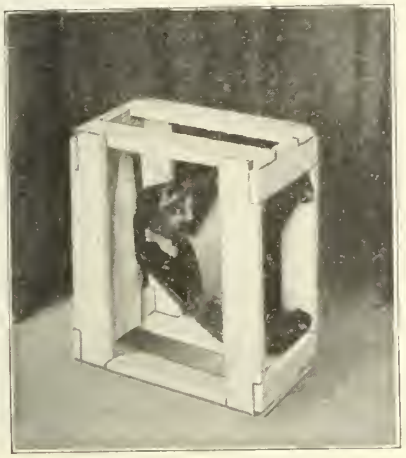


Fig. 1—The three-way notched corner crate for automobile transmission case

Just such a service which was performed a few months ago at the laboratory of the Chicago Mill and Lumber Co., Chicago, in response to a letter of inquiry to the sales department for prices on fifty thousand boxes for carrying automobile transmission cases, is described in "Boxes," the house organ of the company. The customer did not know just what he wanted. He needed a low-priced box that would carry the transmission cases safely, but left the details of construction to us. He did, however, suggest using a certain type of box because he had been led to believe that it was the lowest priced box obtainable for this particular service.

A Visit to the Plant

The sales manager turned the problem over to the research department and requested that an engineer be sent to study the problem. At the customer's plant it was developed that the box of the particular type desired was estimated to cost twenty-eight cents. In making his bid on the contract, the customer had used an estimated price of twenty cents, and any amount in excess would mean a loss upon the contract. Consequently the problem was a satisfactory package at a cost not to exceed twenty cents.

The outcome of the study was a nailed crate which cost fourteen cents for material and three cents for assembly, making a total cost of seventeen cents.

In view of the production outlined by the customer's engineer, it was necessary that something in the way of a nailing form be designed to expedite shipping.

How the Study was Made

The weakest part of a crate constructed of fairly clear lumber is at the corners where three frame members meet. It is possible to join the three frame members at the corner sixteen different ways, any one of which would be a three-way construction. The three-way corner which gives the greatest efficiency is one in which each member is nailed to another member and has a third member nailed to it. It is a common type but its value is not appreciated by some, as is evidenced by the many examples of crates of inferior yet more expensive construction found in freight houses.

Designing for Rigidity

The ordinary three-way construction is not always 100 per cent efficient, and it is frequently necessary to add diagonals in order to get a balanced crate. But diagonals run the cost up, and where cost is the controlling factor, it becomes necessary to try another line of attack in designing for rigidity.

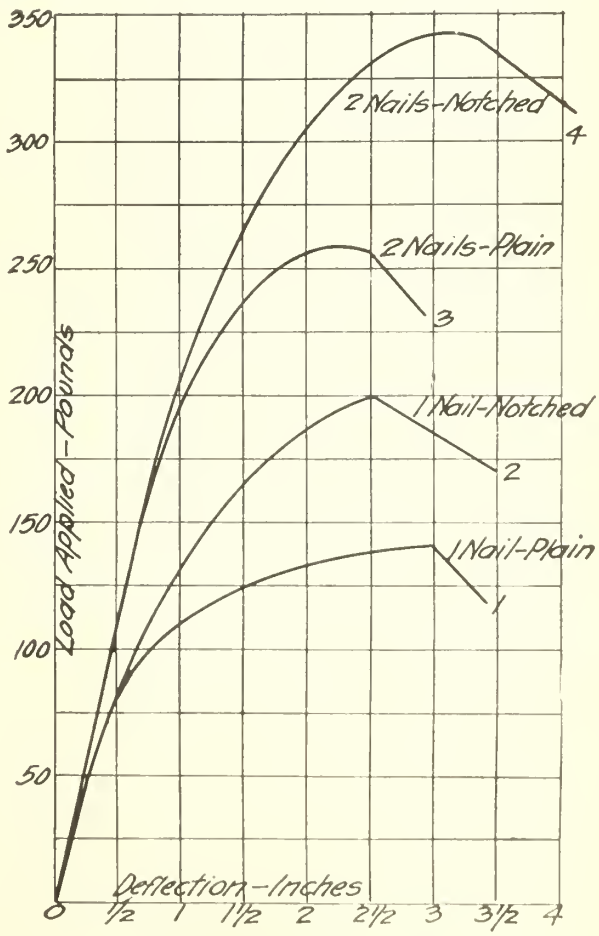

Chart of curves, showing additional strength obtained by using the notched corner

Our attack centred on the weakest part of the crate and the three-way notched corner construction shown in Fig. 1 was a step toward the more efficient construction which we needed.

Compression Tests

Just how much rigidity was added by the notched construction is clearly shown in the curves of the accompanying chart. These curves were obtained from the cornerwise compression tests of crates with and without notched corners, and with one and two nails in each member of the crate at the corner. The materials used were 3 x 5/8 inch lumber, and 5-penny cement coated nails. Fig. 2 shows the method of conducting the test. The load was applied at the corner and in the direction of a line passing through a point at the centre of the crate.

In these curves the maximum load was reached at a deflection of approximately 2½ inches. The difference in maximum loads of curves No. 2 and No. 1 and curves No. 4 and No. 3 is about the same, it being 63 and 73 lbs., respectively. This increased load was taken by the notch. In the one-nail crate the strength was increased by 46 per cent, and in the two-nail crate, 28 per cent.

The Notch Eliminates Strain on Nails

There are other features about the notched construction that are highly desirable in crates. A study

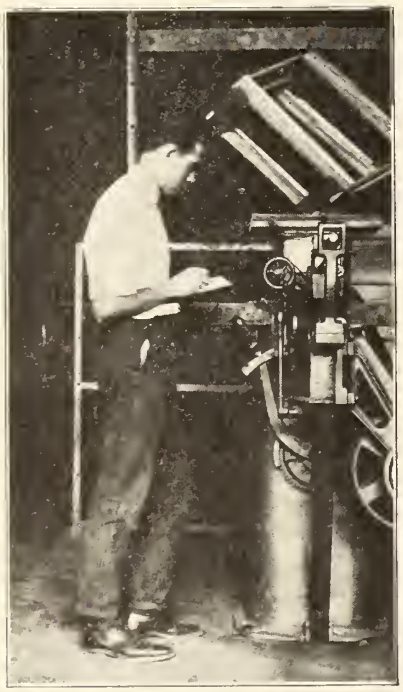

Fig. 2—Applying the load in corner compression

of Fig. 1 will show that the notch provides a shoulder upon which rests the adjacent member, and when the nails are driven there is no tendency to bend nails which already been driven, because the blow of the hammer is taken by the shoulder.

The principal factor of strength desired in this crate is resistance to loads piled on top of it. The notched corner is especially adaptable for this, because all the weight is taken by the notches and none by the nails.

How Nails Were Saved

Having obtained a crate of increased strength by means of the notch, we began to investigate the possibility of saving nails. Again referring to the chart and curves No. 2 and No. 3, it will be seen that the notched corner with one nail is approximately 80 per cent as strong as the regular three-way corner with two nails.

The article to be crated was a casting, and could take a considerable amount of the rough handling incurred by the package without damage. But a large per cent of the cases were to be shipped in carlots and, consequently would not receive the rough handling of less than carload shipments.

In view of the limited handling the crate would undergo, and the fact that a notched three-way cor-

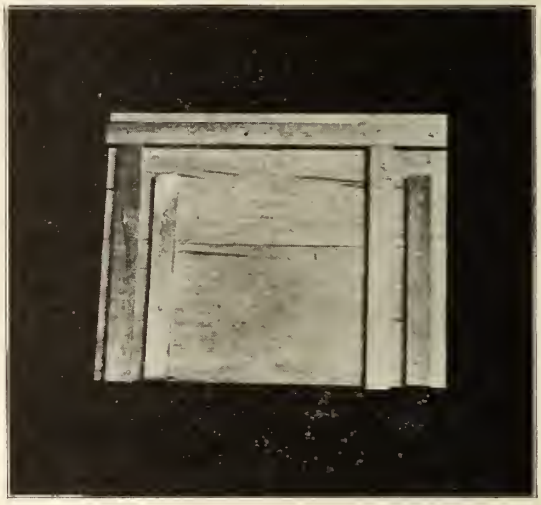

Fig. 3—Nailing form that saves time and labor

ner with one nail is 80 per cent as strong as the regular three-way with two nails, it was decided to use one nail in the corner construction. By doing this, the number of nails was cut down 50 per cent and at the same time 50 per cent of the labor of nailing was saved.

Tools for Engraving Metals

Poulamond, N. S.,

Editor, "Canadian Woodworker."

Can you tell me where I can secure some engravers' tools for doing some fine letter work on metal?

Sincerely yours,
Chas. N. Pertus.

As far as we can ascertain engravers' tools are neither manufactured nor handled in Canada. If you will write any one of the following firms, it is just possible that they will be able to take care of your requirements. Acme Diamond Tool Co., New York City, N. Y.; Wm. Dixon, Incorporated, New York City, N. Y.; Hammel Riglander Co., New York City, N. Y.; or Sussfald, Lorsch & Co., New York City, N. Y.

The new Coliseum at the Canadian National Exhibition is the largest and most costly building ever erected on a permanent Fair grounds. It cost $1,000,000, while an additional $250,000 is being spent in equipment.

Machinery & Equipment

Jig Saw With New Features

The Oliver Machinery Co., Grand Rapids, Mich., have just placed on the market the Oliver No. 173 self-contained jig saw, which is claimed to be a radical departure from anything heretofore offered for scroll saw-work. The object of this machine is to do jig or scroll sawing in wood for such kinds of interior and exterior scroll work as occur in furniture-making, cabinet-making, musical instrument shops and, indeed, all plants where irregular sawn wood

Oliver No. 173 jig saw

is used. The unusual features of the machines are the absence of overhead mechanism, the guarding of all moving parts and the lack of tension in the saw blade.

The saw has capacity operating from the front of the machine up to 36½" between the saw and the column, but the saw may be operated from the side, that is, the saw turned at 90 degrees, so that work of almost any length or practical width may be sawn. The highest work that can be taken under the guide is 10". The stroke of the saw blade itself is 3" and saws up to 18" may be used. All moving parts are very carefully guarded, and the saw is operated without tension in the blade so that a broken blade will not be likely to cause an accident.

The convenience in inserting saw blades in place appeals to the operator because the saw can be removed and replaced in very little time. The clamping device below the table is automatic and the sliding block in the upper guide way provides a very rapid and convenient method for inserting the saw. Saws may be turned ¼ way around operating standing against side on machine or at the front of the machine thus increasing, very materially, the length and width of stock that may be worked on this machine.

There is no overbalance load which insures a steady, quiet running, vibrationless machine resulting in fine and better work.

The jig saw is self contained when belt driven as well as when motor driven. All parts are made interchangeable and all bearings and movable parts are made to compensate for wear. The pitman and the cross head are made of aluminum which is light in weight yet very rigid. Complete and easy control of the machine is obtained by means of a foot lever located conveniently for the operator.

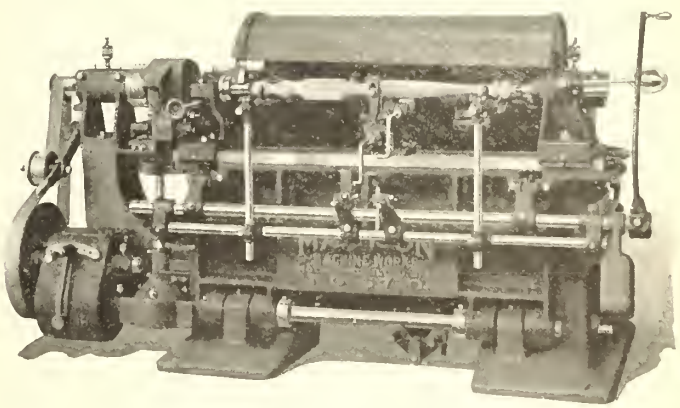
The slide dumping device in the table in front of and around the saw, with a knob on the under side, may be drawn back to permit small cuttings to drop through the table and out of the way when doing intricate interior scroll work. A continuous flow of air is directed to the front of the saw.

The table is of cast iron, strongly ribbed, size 30" x 34", mounted on rockers so as to tilt 30 degrees to the right and to the left. It may be locked in any position by means of clamp screw and hand wheel.

When direct motor driven a flexible coupling is mounted on the shaft for direct connection to the motor. The speed of the shaft is 1,200 r.p.m.

New Automatic Shaping Lathe

The illustration herewith shows the new model 57-D Mattison automatic shaping lathe being marketed by the Mattison Machine Works, Rockford, Ill. This new model lathe has been completely re-designed from the ground up. Even the main base is brand new, being made heavier and more rigid than it was before, with better provision for getting the shavings away, providing more room and better clearance for the various attachments, etc. Main bearings have



The 57 D Mattison automatic shaping lathe

been improved by making them longer and heavier, providing larger oil chambers and adding drip oilers.

The five-step cone feed pulley requiring the drive to come from a countershaft or jackshaft has been done away with by substituting a single pulley with belt tightener. Sliding gears running in a bath of oil provide the speed changes for the feed. The speed of the feed shaft and bevel gears connected to upright shaft, has been cut in half, reducing wear and giving smoother running. The head stock gears are placed in permanent adjustment before they leave the factory and never have to be disturbed or interchanged when substituting work-holding devices, thus eliminating the danger of getting these gears out of adjustment and causing undue wear. The car-

riage is heavier, yet better balanced, and easier to handle.

The hollow chuck attachment has been greatly improved and simplified, and not only can be operated faster, but can be easily removed or attached by one man. An automatic centering device is provided when the head centre is used in combination with the chuck. This combination makes for quicker handling and also saves stock on a great many styles of turnings. The chuck is mounted on an extension plate which permits of using the regular tail stock in combination where it is desirable on certain classes of work. New locking device on chuck jaws allows stock to be revolved in either direction without danger of the grip loosening. The dust hood has been improved and is now provided with a movable damper which can be set to confine the suction to just the length of cut being taken.

Many other refinements along the line of those mentioned have been applied, which go to make the machine easier and quicker to handle, increasing capacity, eliminating.

Westinghouse Motor Starters

Of interest to woodworking plants using electric drive is a line of motor starters, affording complete protection to the operator and the motor which has been developed by the Westinghouse Electric & Manufacturing Company. These starters are fully described in a publication, folder 4,500, recently issued by the Westinghouse Company. Altogether there are four types (WK-10, 20, 30, and 100) of these starters with capacities ranging from the smallest motor up to those of 15 h.p., 550 volts. The mechanism of each type differs somewhat from that of other types, but the chief features of safety and reliability are common to them all.

The construction of these starters is extremely simple, their first cost is low, and, at the same time, they possess many protective features. All of them are equipped with a device for locking the switch in the "off" position to protect those working on the machines. A door, which is so interlocked with the switch mechanism that it can be opened only when the switch is in the "off" position, covers those parts requiring inspection and occasional renewal.

The motor is protected from overload, both when starting and while running, by means of time-limit thermal cutouts or relays. The time lag of these thermal cutouts allows reasonably high starting currents or momentary overloads which do no damage to the motors. When subjected, however, to a continuous overload sufficient to overheat or damage the motor, the outlets or relays serve to quickly open the circuit. The capacity of each starter can be changed within its range by substituting the proper thermal relays or cutouts.

Since the switches are quick-make and quick-break, they can easily break the locked current of the largest motor having a normal current within the limit of the rating of the switches. All these starters are of the single-throw type, the motor being started by turning the switch to the "on" position and stopped by turning it to the "off" position. The entire switching mechanism can be inspected by removing the screws that hold on the cover, and the switch can be removed and renewed from the front without disturbing the box of circuits.

The Latest in Kilns at the Forest Products Laboratory

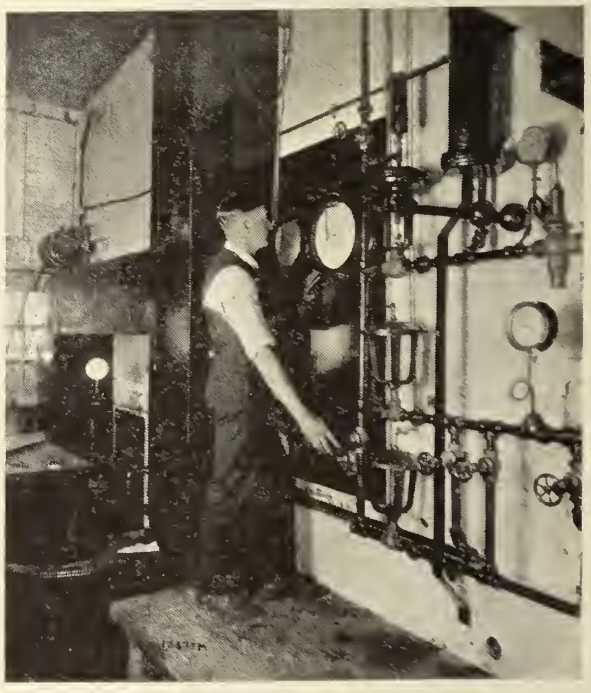
The new kilns at the Forest Products Laboratory, with which the action of any commercial type of kiln may be reproduced, will be of special interest to those taking the kiln drying course at that institution.

Each of the three fundamental factors in drying wood, moisture, heat, and circulation, is perfectly and easily controlled, not only for duplicating any particular type of kiln-drying action, but for any modification that the experimenter may wish to try out.

The new kiln, while built for experimental purposes, is a regular sized unit intended for practical work under any condition which may be met in commercial operation. The kiln is not so much for comparing the relative efficiency of different types as to make possible studies by which these various types may be improved and the best drying rates worked out. It is intended also to use the kiln as a demonstrator in the courses of dry kiln operation.

In designing the kiln, special attention was given to the production and control of the air circulation; two types, internal and external, of blower or forced draught equipment, are provided, and further control is possible with the series of air ducts, dampers, and vents.

The four internal blowers are all mounted on one shaft below the lumber and are driven by a motor located outside the kiln. Heating coils are on either side of the blowers. Reversing the motor reverses



Operating room of the new demonstration kiln at the Forest Products Laboratory

the action of the blowers so that the air may be either forced inward through the lumber or drawn outward. The course of the air is further directed and made more uniform with a special arrangement of baffles and air distributors. This reversal of circulation produces more uniform drying with less power and in less time than is possible with a non-reversing circulation. The internal fans are particu-

Upholstering and Trimming

Application of Down as a Top Stuffing

Thin Quilted Pad of Down Over Springs and Hair is Advantageous—May Be Used on Any Chair of Roomy Dimensions

The chair frame, illustrated in fig. 125, introduces a new theory of comfort into the discussion of the application of down as a top stuffing. This chair is upholstered in the early stages in all respects the same as the one described in connection with fig. 118 in the June issue, in which the previous article of this series, reprinted from "The Upholsterer," is published.

The seat has a spring edge built up in the usual way with a very soft stitched edge and hair understuffing. No description, therefore, need be given in connection with figs. 126 and 127, nor is it necessary to describe the placing of the pillow springs in the back and the soft upholstering of hair which overlays the springs.

Fig. 128 shows a quilted pad of down attached to the back as a top stuffing. This pad, which is thin, is made knife-edged, that is, without inserted borders, and is filled with a very light filling of down and either tied at intervals to prevent shifting of the down, as shown in fig. 131, or sewn across by means of a sewing machine, with a very slack top-thread tension, creating a loose type of quilting, as shown in fig. 132.

This pad, as indicated in fig. 128, is tacked over the under-stuffing to make a soft surface next to the cover. It goes without saying that for a surface of this kind the cover must be left fairly slack, so that the fluffing of the down will fill it comfortably, but always avoiding that degree of tightness which would nullify the advantages of employing the down pad.

The arms and wings are double-stuffed very softly and built up as shown in fig. 129. Over this is placed a light padding of hair, as shown in fig. 130. The down-filled pads, similar to those shown in figs. 131 and 132, are made a little over size, that is, the pad for the wing would be made about one inch wider than the actual size of the wing, and that for the arm possibly two inches over size each way. These are then attached, as shown in fig. 133, in such a way that there shall be no wrinkles that will be perceptible under the covering but retaining so far as

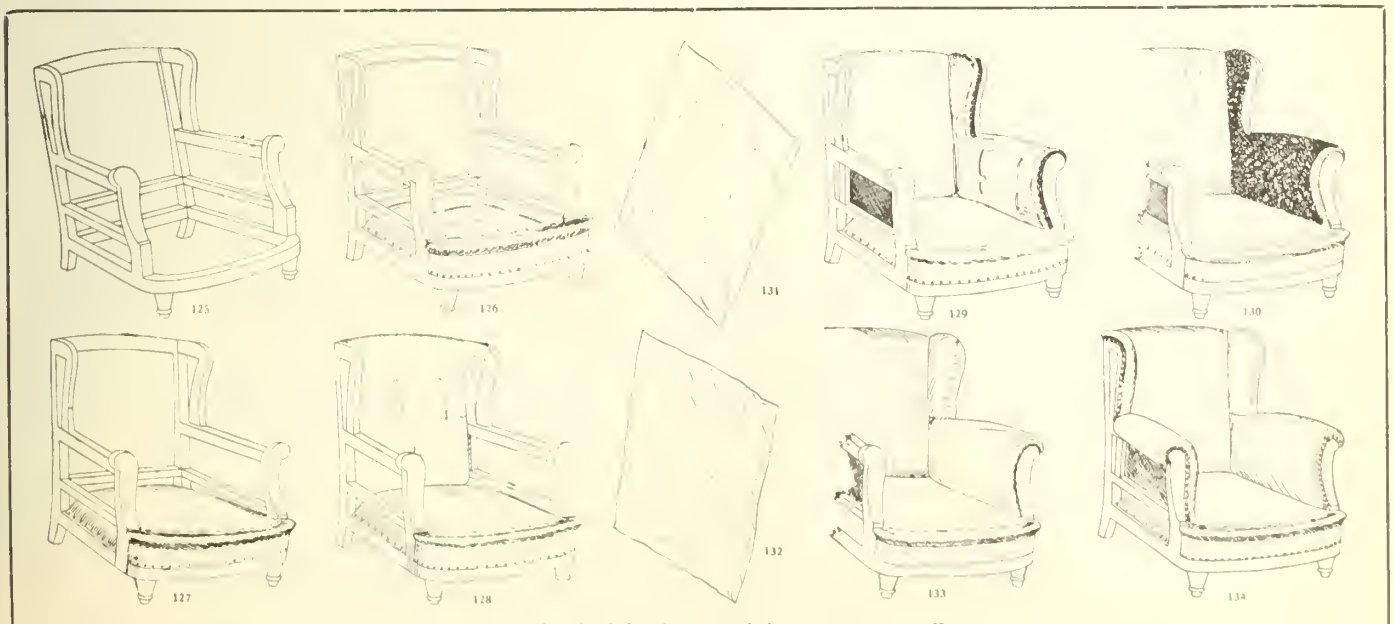
Where Money Can Be Saved

Special Machine for Cutting Burlap Dispenses with High Priced Labor—Eliminates Waste and Increases Production

Keener competition and consequently the necessity of reduction in costs without impairing the quality of the produce, has spurred many modern manufacturers to solve and adopt improved methods in the cutting and tacking of burlap.

Formerly the upholsterer was obliged to cut the burlap for a job and also to tack it on the seat, arm, back, etc., of the furniture. This was a very expensive method and involved a waste of materials. In general, the piece worker under this system had neither the time nor inclination to make the most economical use of material. This induced a few thoughtful factory managers to start special burlap-cutting

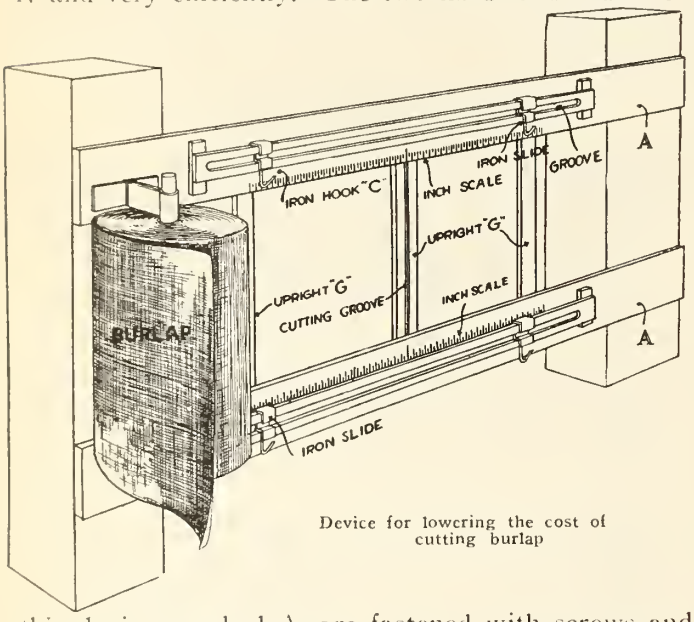


The various stages involved in the use of down as a top stuffing

and tacking departments which have proven very practical and successful. Experience proved that high priced mechanics were not needed for this work but that it could be done very satisfactorily by boys, properly trained and supervised.

The first essential for installing such a department is a competent cutter to prepare diagrams and size-cards for each style made, tacking a similar pattern where he can use waste cuts from one on another. After he has cut all pieces needed for a certain style, he lays them together in order to find the general size needed. A card index is then made showing the general size of the burlap needed on this particular pattern and also a diagram showing how the different pieces have to be cut out of this large one without waste. The actual cutting is divided into two parts. One boy cuts the larger sizes and another one lays them out and cuts each into smaller parts as per diagram.

In Figure 1 is shown a practical device which permits the cutting of large pieces of burlap very quickly and very efficiently. The two hardwood boards in



Device for lowering the cost of cutting burlap

this device, marked A, are fastened with screws and bolts upon a heavy frame. Each board is marked in such a manner that is resembles a rule showing an inch scale on each side from the centre. The sliders, marked C, are made of iron and run in a groove which makes it possible to set them at any size desired.

If a boy needs, for example, forty pieces of burlap sixty-two inches long, he fastens the burlap on the first hook towards the roll and runs the hooks to the centre of the upright G. He then moves the second hook to thirty-one inches from the centre and fastens the burlap, turning it back and refastening it again at the first hooks in the centre. He continues to move forward and backward until he has the necessary number of pieces.

The cutting can be done either by hand with a regular knife or by a special knife running the entire length of upright G. These larger sizes of burlap are given to another boy, who refers to the index cards, showing him how to cut the larger sizes into the different smaller pieces needed for the pattern. Such cutting is done by an electrically driven cutting machine which makes it possible to cut through layers of burlap ten to fifteen inches in thickness.

The saving in time and material is very considerable. This device and the standardizing of work can also be adopted successfully by the smaller factories. After the burlap has been cut, boys tack it on the frames which are received from the spring-setting department. They even upholster the front seat roll. Of course, this requires a little teaching and supervising, but it is worth while. Considering that formerly upholsterers received from $1 to $1.25 for this work, the economy is evident. It has the other advantage that every upholsterer is free to do strictly upholstering work, insuring a greater output and production at lesser cost. Twelve boys properly trained can keep about seventy upholsterers busy and amply supplied with work.

It is, or course necessary that the production manager watch this department for the first few weeks very carefully in order to insure a steady and easy flow of work. The entire furniture industry needs standardization. Frames can and should be constructed in such a way as to allow the upholstering of parts so that they can finally be assembled.—O. Rene Sulk, in the "Furniture Manufacturer and Artisan."

Application of Down as a Top Stuffing

(Concluded from previous page)

possible the full benefit of the down, when the covering is tacked into place, as shown in fig. 134.

The completed chair, should give little indication of the presence of down on the arms, wings and back, it merely carrying the appearance of a soft, comfortable, stuffed-over type.

The down pads described in connection with this chair can be used on any chair of roomy dimensions and our use of them in connection with this chair is not intended to convey the idea that this is the only style we have illustrated for which this type of down cushioning would be suitable. We have merely chosen this particular chair for the purpose of explaining the method of utilizing down pads as a top stuffing.

MARIETTA WOOD AND METAL FINISH SPECIALISTS

Enamels for Wood and Metal Work

Our highest grade enamel for interior and exterior woodwork is "SPARTANITE."

This is unexcelled for beauty, elasticity, long-wear. Made in White and Ivory, gloss and egg-shell, or can be tinted to suit any color scheme.

But we also make special enamels for manufacturers of wood and metal products.

Put your enameling problems up to us.

Troubles With Varnish

The Difficulties an Unskilled Finisher Meets—Thinning with Turpentine Develops Defective Work

By A. Ashmun Kelly

In many instances an unskilled varnisher is unable to rub cabinet varnish after it has stood ten days to dry; it seems to be too soft. Sometimes he thins down his varnish with a little turpentine, in order to secure a harder surface for rubbing in from seven to ten days. Some of his numerous advisers (whose advice, as a rule, has been very costly and unsatisfactory) told him not to thin with turpentine, as that will injure the gloss. This is very true, though inasmuch as he wants to rub out the gloss this objection does not stand. Finally he concludes, "In order to become a good varnisher I must understand the nature of varnish troubles and how to overcome them."

There is something singular about this matter of workmen giving expert advice that does not seem just right. Either the giver does not understand the subject himself very well, or he intentionally misleads the man. I know that many experts will not impart trade secrets or routine knowledge to fellow-craftsmen. This is the result of either one or two things, viz.: they wish to have it appear that they possess superior and restricted knowledge bearing upon certain matters, or they have a jealous fear of extending competition in their line if they enlighten others who do not have the same amount of expert information. It is a pleasure to some, be it said in justice to such, to impart information.

There are two things that will usually produce a first-class varnisher, a natural aptitude for such work, and patient practice. No amount of mere telling, however correct the information imparted, will do this. The telling, if correct, has its uses, and is to be desired by the learner, but it must be coupled with practice, as stated. When this workman was told that turpentine would impair the gloss of his varnish—a fact, let us assume, he did not know before—it was very valuable advice.

More might have been said in this connection, such as the fact that where rubbing was to be done the mere loss of gloss by the addition of turpentine was not a vital matter. But that he had to thin it out showed that something was lacking in the varnish, for it should work perfectly when taken fresh from the can. Or, if thinning was necessary, owing to the varnish having lost some of its liquid contents by evaporation, thinning out was correct, but it might be that the use of benzine in place of turpentine would have answered better, for it would enable the user to readily brush out the varnish, after which the benzine would evaporate and not affect the gloss.

Thinning is not Always Effective

Sometimes turpentine is added in order to hasten the drying, and driers, too, are sometimes added for the same purpose. But turpentine does not cause the varnish to dry any quicker, though it seems to help that way. Sometimes the trouble with a varnish not spreading properly is caused by weather conditions, especially cold, when heating the varnish is much better than thinning it. This may be done by placing the can of varnish in a vessel of hot water. Varnishing done in a damp or cool room will cause troublesome spreading. Or if the room is warm and the varnish cold, the latter will work poorly. Warm both varnish and room? Yes, and the article that is to be coated should be warmed to a proper degree, say around 72-deg.

Flowing varnish is most injured by thinning, because it contains much oil. Another danger to be apprehended is that the turpentine may not be pure, but contains more or less mineral oil. We have tested samples of turpentine that showed as much as 50 per cent of such adulteration. The effect is found in the difficulty of rubbing, the varnish remaining too soft. Such varnish would not dry hard enough to rub well, and it might even remain undry and sticky. The effect of petroleum oil in paint or varnish is to impart elasticity or pliability, where that quality is somewhat lacking. But a very small portion does this. It is said that only an expert knows how to use doped goods and get away with it. I doubt his ability to do so. Doped goods are always treacherous.

Premature Rubbing

Too often varnish is rubbed prematurely; two days may be allowed for some grades, yet a day or so longer would give better results, but time is so costly now. Then varnishes differ so in drying qualities; of course, some dry much quicker than others. Some varnish will demand as much as a week, or even longer, while some other grades will dry all right in one day. New varnish does not dry nor work as well as that which has matured with age. Age improves the quality, if the air is kept away from it. To get age, the varnish, after its making, must stand in the tanks a long time, and this is expensive, as may readily be seen. The quicker the varnish is gotten into the market the better it pays the producer. However, if the quality is low to begin with, no amount of age will make it a good varnish. It is like a violin, though it is now said that age has nothing to do with improving the tone of that splendid instrument. At any rate, we know that age has a good deal to do with the quality of a good varnish.

It would be well to buy the varnish in drums and so keep it until it has sufficiently aged—provided that your capital will admit of it. By standing a long time the foots, technical for floccular matter, which comes from the seeds and plant from which the oil is pressed, settle to the bottom, leaving the clear oil above, and this may be drawn off into another and clean vessel. This clear, settled varnish will give you finer work, in that it is free from specks, and these are one of the worst troubles that any varnisher meets in applying a good gloss finish to his work.

I ought to say here, having omitted to say it in its proper connection, that if the finisher has been

nsing his varnish too heavy, that would cause poor drying, and also tempt him to thin it more. But a thin varnish does not have proper body, as a full-bodied varnish does. The thin varnish will spread out well, but will lack luster, where that is desired. If the varnish is very heavy it will likely show brush marks, especially when an inexpert workman uses it.

Use a varnish that is best adapted to the character of the work. Allow ample time for its drying. If it goes on a wood that contains considerable filler, the drying will be slower, for which allowance must be made. The better the grade of varnish used the better will be the results, providing you understand its handling. The poor varnishes give the most trouble. I have listed different sorts of troubles that the varnisher meets with during his life experiences, provided that he is unfortunate enough to come in contact with them all. Just whether all varnishers do meet with them all I cannot do more than guess, and my guess is that they do, because every varnisher works under a certain condition of things that insures trouble as well as success in his labors. All have the weather conditions, all have good and bad varnishes to handle, all have to rush things—nowadays at least.

Seedy Varnish

Several different troubles arise from doctoring a varnish, some of which have been named, but there is another called seediness; thinning the varnish will give this effect. This means the appearance of a multitude of tiny specks on the gloss finish, and which practically ruins a finish of this kind. These specks are simply very small bits of undissolved gum. Heating the varnish, instead of thinning it with turpentine, would dissolve these bits of gum. It should be remembered that varnish is made with heat, that the hard gum is melted and made fit to mix perfectly with the oil and turpentine. When the varnish is subjected to excess of cold, or where it is not sealed against the air, this gum forms these tiny atoms, and needs melting again. Thinning will not do it.

It is well for the varnisher to know how varnish is made, for this will enable him to avoid mistakes in its handling, as he too often does. The ingredients are few and simple, and the process of manufacture is not so intricate that the average mind cannot comprehend it. It is a delicate liquid, and needs to be cared for properly, as well as be applied carefully, if one is to get the best and most satisfactory results. There is not one cause of ill success with varnish that is not understood by the expert varnisher. Unfortunately, he is not always in a position to avoid more or less of the varnish troubles that come to him. For instance, his shop may not be right; there are the elements of fresh air, ventilation, proper degree of warmth, absence of excessive humidity, time allowance for work, the right varnish for the work, and many more that are only too well known and hard to command.

If the expert finds troubles, what is the man of little experience to expect? It is thought by many of the latter class that the expert never has any varnish troubles to contend with. Let him consider that as there is no royal road to learning, so also there is no easy cut to success in varnishing. Practice, practice, practice—that is the password, coupled with an eagerness to learn all possible from those willing to impart practical information who possess it. Considering that others have succeeded, there is reason to believe that you also can succeed.—Veneers, Indianapolis.

Developments in the Use of Wood Lacquer

How Should Wood Lacquer be Applied to Obtain the Best Finish?—What is the Proper Spray Equipment and How Should it be Handled?

The development of wood lacquer as a finish has brought with it, as was to be expected, certain difficulties and uncertainties which every finisher handling the material is bound to come up against. However, it is certain that wood lacquer for many purposes is an ideal and the most easily applied finishing agent, provided it is handled with a proper knowledge of the factors involved in its application. Every finisher is interested in it and for that reason two articles from a recent issue of "The Furniture Manufacturer and Artisan" are of special value. The first, by S. L. Dickenson, is as follows:

In explaining the use of wood lacquer, it may be well to start at the beginning of the use of varnish. Years ago, before the linseed oil varnish was used, furniture was finished with shellac by French polishing. Although this grade of finish went very well in European countries, for some reason or other it does not stand on this continent, therefore the oil varnish finish was superior to French polish.

When the different furniture and piano factories changed from solid wood to veneered parts, the trouble began, and even today you will find on the varnished piano that the moldings and solid wood parts stand up much better than the veneered parts do.

There are several reasons for this. In the first place, the glue under the veneer generally finds its way to the surface on the outside of the veneer. This can be determined by laying a wet piece of paper on the veneer and weighting it down over night and the paper will not come off the next morning. This glue under the veneer is affected by moisture almost as much as salt, and as oil varnish is not impervious to moisture, the moisture finds its way to the glue and immediately starts the action of shrinking and swelling. This trouble is sometimes made worse by the fact that the finisher will use a stain which contains an excess of bichromate of potash or a strong alkali. In either case, the oil in the filler and oil in the varnish will to some extent saponify in the pores of the wood; thus on the end wood streaks in mahogany you will have more trouble than on the side grain. This, no doubt, is the cause of more or less of pin holes. Someone adopted the use of shellac, a very thin coat on the stain under the filler, in order to eliminate this trouble. Although this would more or less eliminate that trouble, the acid in the shellac would in a great many cases turn the pores gray. Others put this coat of shellac on top of the filler before varnishing, but this simply would help you out of one trouble into another. If this coat of shellac was too thick, it would chip off and shorten the varnish.

Oil varnish starts to oxidize the minute it is applied and from that instant the deterioration commences and when the oil is thoroughly oxidized the life of the varnish is over.

Some years ago, the writer used to wonder why a

lead pencil was the only piece of wood glued up of two parts that would stay straight and often wondered how it was done. On finding out that this was done with a cotton solution, I immediately went to work to produce a wood lacquer to use in commercial finishing. Working on the theory that a piece of wood is absolutely permanent and if you can keep it wet all the time or dry all the time it will never rot or deteriorate in any way. The pile in the water will rot off at the water's edge, owing to the fact that it is wet and dry more times there than anywhere else. The same condition holds good on a post in the ground, as it will rot off at the surface of the ground.

Cotton being a wood fibre in the clearest form, under the microscope will resemble a glass tube. This cotton put in liquid form is nothing but a liquid wood fibre. When the solvents dry out of this liquid wood fibre there is absolutely nothing left to deteriorate as it is waterproof, will seal the pores of the wood, is more or less elastic and will not crack or scratch.

On a test by a large concern, a panel finished in wood lacquer was frozen in a solid cake of ice without cold cracking it. A piece of cross-banded stock that is thoroughly covered with lacquer (probably the best way to do this would be by dipping) can be soaked in water over night without starting the glue joint.

Spray Essential for Lacquer

Lacquer was never brushed successfully. The use of lacquer on furniture would never have developed to its present magnitude had it not been for the spray, as lacquer will dry very quickly and cannot be brushed on successfully for more than one coat. Spraying, however, has solved this problem. On the other hand, spraying, if not done properly, will not only waste material but will spoil the work and give wood lacquer a black eye. Too much care cannot be taken in the application of lacquer. Probably the best spray to apply lacquer with is what is commercially known as an outside mixer, as the air carries the fluid tip at the angle of about 90 degrees and syphons the material to the tip and then atomizes it. This type of spray is manufactured by a number of concerns and can be used at a very low pressure, therefore the atoms of lacquer do not dry before they hit the work. On an actual test, in a piano shop in New York City, the writer applied six coats of lacquer at a pressure of eighty-five pounds with an inside mixing spray and there was not enough body on this work to be rubbed. On taking a spray that mixes outside and applying six coats of lacquer at a pressure of thirty to thirty-five pounds, using a very large fluid tip, it had an excessive body on the same class of work, under the same conditions. The reason for this was that about one-third of the material went up the fan. This way it would make the cost of lacquer prohibitive. An outside mixing spray at a pressure of thirty-five pounds will use probably two cubic feet of free air per minute. The same make of spray with an inside mixing system will use six cubic feet of free air per minute, discharging at the pressure of seventy pounds; thus it not only uses more lacquer but takes more power.

A Good Finish

The following is probably the best way to obtain a good finish with wood lacquer: Stain and fill in the regular way. Apply four or five coats of wood lacquer, thinned properly, allowing about two hours between coats, and this can be rubbed twenty-four hours after the last coat, thus saving from 300 to 400 per cent of the time in your varnish room, thus cutting down the overhead and making more turnovers in a specified time. When this work is lacquered and rubbed, it can be subjected to all kinds of rough usage. It will not scratch and absolutely will not press-mark. Perfume or anything that contains grain alcohol will have no effect on it. Age does not affect lacquer the same as it does varnish.

Finish of Furniture and Similar Articles by Compressed Air

The other article referred to in the introduction discusses the use of spray machines for the application of wood lacquer. Its author, W. J. Smart, writes as follows:

The use of the spray machine or air brush for finishing furniture, cabinets, pianos and all manner of wood products is today recognized and appreciated for its merits, superiority of finish, economy in time, saving in cost of rubbing and polishing and saving of rental and floor space, for when the spray system is used the products are turned out so much faster that they may justly be considered as a rent-saving element, as well as time and labor saving.

The writer has in view a case of a recent New York City manufacturer, who was asked by a representative of one of the largest department stores how soon he could fill a good sized order for small tables. He wanted them in twenty-four hours. The manufacturer started in to state how impossible it was, when the salesman interrupted him and said, "Promise the goods, I will see that you get them out."

The tables were finished with four coats and delivered the following day. Needless to say, both the customer and the manufacturer were exceedingly pleased. Were the tables finished by the ordinary process of varnishing it would have required ten days.

The writer does not wish to state that wood lacquer will supersede varnish altogether for finishing wood products, but does consider it in order to state that the use of wood lacquers is largely increasing and that the advantages cannot be ignored by wise, progressive and up-to-date manufacturers.

Any number of coats of wood lacquer may be applied the same day, where only one coat of varnish per day can be applied.

Wood lacquer is moisture proof and protects glue joints—varnish does not.

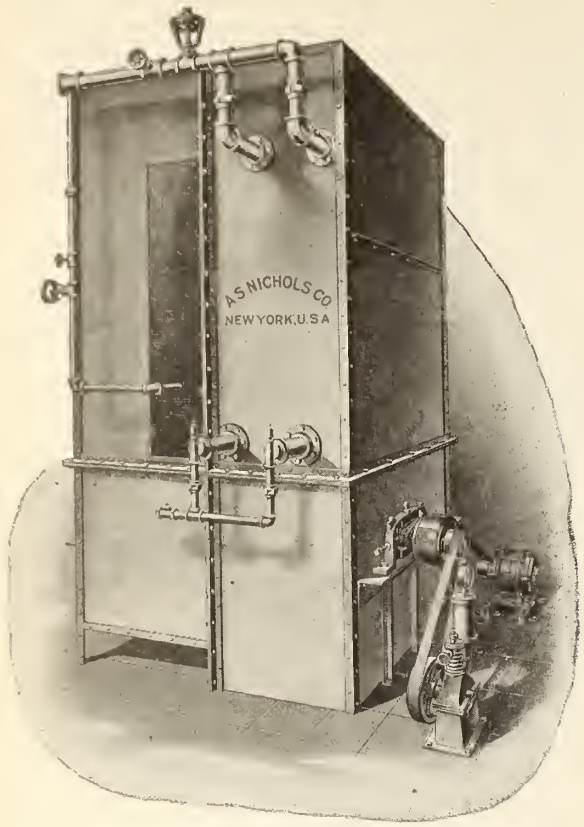
REEDS

We deal in all grades of Chinese, Holland and German Reeds and can ship to any destination from Toronto or New York, or direct from point of origin.
We are also dealers in Rattans, Turpentine, Cotton Linters and Cotton Waste. Prices and complete information upon request.

E. T. CARTER & CO., LIMITED
84 FRONT ST. E., TORONTO



Vertical Equipment Floor Space 4 x 6 ft.
Crated and shipped complete ready to set on the floor outside of your varnish room

Set Outside Your Varnish Room

The money a Nichols Paint and Varnish Dryer saves will pay for the equipment in one year.

This is not a wild statement but one we have proved time and again to manufacturers in practically every branch of the woodworking industry.

The Nichols Vertical Paint and Varnish Dryer is a complete unit of fan, motor, heaters, air compressor, with automatic humidity and temperature controls. A new rotary, humidifying air washer which eliminates all dust and dirt and does away with all spray heads, pump and connecting piping.

The equipment is manufactured in sizes suitable for all requirements.

Let us analyze your particular needs and quote prices on same.

A. S. NICHOLS COMPANY

Aeolian Hall

33 West 42nd St., New York City

Manufacturers of dryers for lumber, veneers, glued stock, varnish, paints, enamels, etc.

Increasing speed and reducing costs while making certain highest quality work, in your finishing room with the

DeVilbiss Spray-painting System

Whether you manufacture phonograph cabinets or chairs, metal cabinets or brass beds; whether you varnish, enamel or lacquer those products, one DeVilbiss spray operator will do 4 or 5 times as much work as a brush finisher in the same time.

On every class and grade of work the sprayed-coating will be of highest uniform quality—free from brush marks, runs, fatty edges and like faults. .... DeVilbiss exhausting equipment will insure a clean, healthful place in which to work, and reduce the fire hazard.

The outfit will be on the job every day, and cost little to operate and keep up.

These savings and advantages can be had in your finishing room, in the same profitable degree they are now enjoyed in thousands of wood and metal-working plants of every kind.

Let us mail you further particulars that meet your individual requirements

The DeVilbiss Mfg. Co.

3718 Detroit Ave. *Toledo, Ohio, U.S.A.*

Manufacturers also of DeVilbiss Spray-painting portable equipment for spray-painting factory interiors and exteriors at a big saving in time and cost.

Veneers and Panels

Conditions Affecting the Adhesive Strength of Glue

Adhesive Property is the Most Important Characteristic—The Effect of Glue Concentration, Heating and Temperature Conditions, Properties of the Wood and Condition of the Joint

By R. H. Bogue, Ph.D*

First article of a series

For all glues that are to be used for joining, panel, or other adhesive purposes, the ultimate criterion for value must, of course, be the actual adhesive strength developed and maintained in service. It would seem at a glance that the importance of this property would be so fundamental that it must inevitably constitute the principal test upon which selection would depend.

This would undoubtedly be the case were it not for the technical difficulties encountered in the making of the test. The importance of the adhesive strength has indeed always been recognized, and relative approximations of this property are constantly being made. A glue foreman will be asked to select between several glues submitted to him, and among other tests he will usually glue up a few joints of the several samples, clamp them up in the usual manner, and after standing a few hours, or a day, break them with a hammer or a chisel, and note which appears to be the strongest joint. But attempts at measuring the joint strength have not been confined to tests by the glue foreman. Many times the trained chemist has bent his energies upon the problem, but his efforts have been rewarded with only a questionable degree of success. He has, however, succeeded in demonstrating that the strength attained in any joint is dependent upon many factors. These factors have been studied, one at a time, and the effect produced upon the joint strength by varying any of them is now quite generally understood. But only by taking the utmost precaution to eliminate every variable, can truly comparative data upon strength be obtained.

Among the factors which have been found to influence the strength obtainable in a glued joint, made with any given glue, are the following:

(1) The concentration of the glue solution.

(2) The time occupied and temperature employed in heating the glue.

(3) The temperature of the glue when applied.

(4) The species, density, porosity, and moisture content of the wood used.

(5) The trueness of the joint.

(6) The amount and method of application of the glue in the joint.

(7) The temperature of the wood when glue is applied.

(8) The rapidity of handling.

(9) The pressure applied to the joint, and its uniformity of distribution.

(10) The time under pressure, and the time of curing.

(11) The temperature and humidity during curing.

(12) The method of breaking the joint.

(13) The hydrogent ion concentration of the solution.

From a survey of the above factors which may influence the joint strength of any given glue, it becomes more easily understood why the strength test has not met with greater success. A perfect control of each of the above mentioned variables is an exceedingly difficult, if not impossible, task. A brief account of the particular influence of each of these factors is given below.

(1) The Concentration of the Glue Solution.—It is self-evident that any wide variation in the concentration of the glue solution used, either above or below a definite optimum, would reveal itself by the production of weaker joints. This is, of course, recognized in a general way, but it is noteworthy that no precise determinations have ever been made, to the writer's knowledge, of the exact relationships involved, or of the exact specifications of the optimum value. In a general way it is recognized that the optimum concentration is very largely dependent upon the viscosity of the glue under consideration; that the higher the viscosity the lower may be the concentration required to produce the best results. But whether the viscosity is the only factor which defines the optimum concentration, and exactly what this concentration is for any given glue viscosity, has not been definitely established. It is common practice to use the lower grades of glues in concentration of from 35 to 50 per cent., and the higher grades at from 25 to 35 per cent. Kahrs* worked out an elaborate scheme by which the most advantageous concentration could be read off on a chart, if the viscosity (by Kahr's glue tester) was known. This was based on the principle that the viscosity was the only factor which affected the most desirable concentration. The chart merely indicated the amount of water necessary to be added to a given amount of glue of any viscosity in order to produce a batch of the specified optimum viscosity.

The writer is of the opinion, however, that such a method, although it possesses some distinct advantages, would not be equally applicable to all glues or to all woods. A fictitious viscosity is sometimes produced, which might alter the optimum value. But of more importance, a viscosity that would give the best results upon maple or other hard dense wood would probably not be so desirable upon basswood, or any other porous type. Glue joins by penetrating

*Industrial Fellow of the Mellon Institute of Industrial Research and Research Chemist for Armour & Co., Chicago.

This article represents a part of the section of the "Glue as an Adhesive" in the writer's forthcoming treatise on "The Chemistry and Technology of Gelatin and Glue," to be published by the McGraw Hill Company of New York

the pores of the wood, resulting in a muliplying of fine interlacing threads of the material extending from one to the other of the two sections of the joint. A degree of viscosity must be selected such that a fair amount of penetration may result. If the glue is too dilute, it will penetrate without any question, but the individual fibrils of glue, when dried will be too thin to impart the greatest strength. On increasing the viscosity the penetration will diminish, but the individual fibers of dried glue will be thicker and stronger, resulting in a stronger joint. If the viscosity is further increased, the penetration will have diminished until the strength obtainable again becomes small. It is on this account that glue is not a good adhesive for metal or non-porous substances. The finer the pores in a wood, the thinner also must be the glue solution in order that a fair degree of penetration may take place. Thus dense woods require a rather thin glue. More porous woods do not require such thin solutions, and if such are used the liquid will sink deep into the wood, resulting in very fine fibers of the dried glue. Consequently more viscous solutions are required for the more porous woods.

The optimum viscosity will depend also upon the use to which the glue is put. Veneer work does not require as viscous solutions as joint work. The glue must be sufficiently mobile to be easily squeezed out during the pressing, or imperfections in the smoothness of the veneer surface will result.

The Time Occupied and Temperature Employed in Heating the Glue.—One of the very common practices which results in a great lessening in the joint strength is the tendency to melt up large batches of glue, and keep in this condition at a relatively high temperature for many hours before being completely used. Often times a large amount of the glue which was melted early in the morning is still unused at night, and goes into the next day's allotment. Such a practice results in a decided weakening of the glue strength. If evaporation is prevented, either by the use of the closed glue pots, or by the addition of water to compensate for that evaporated, then the joint strength may drop as much as 50 per cent., in a day's heating.

The temperature to which the glue is heated and maintained is of equal importance. A few hours of boiling is sufficient to make a glue practically worthless as an adhesive. It is unnecessary even to heat the glue above 140 degrees Fahr., and any higher temperature will result in an unnecessary weakening in the strength of the glue.

(3) The Temperature of the Glue when Applied.—If the glue is at too low a temperature when applied to the joint it will be unnecessarily viscous, and will set too quickly. It should be sufficiently warm so that it will readily penetrate the pores of the wood, and so that it will not set before the joiner is able to finish his manipulation, and apply the pressure upon it. On the other hand, if the temperature is higher than necessary, the viscosity may have become too low; and a loss in strength will also be sustained on account of the excessive temperature, as set forth in the previous paragraph.

(4) The Species, Density, Porosity, and Moisture Content of the Wood Used.—If a given glue at a given concentration and temperature is applied to different types of wood, the strength of the joint may be expected to vary according to the particular suitability of the viscosity used to the porosity of the woods. The wood of that porosity which is most suitable for the viscosity used will show the greatest strength. Density is more or less a measure of porosity. That is, the greater the density, the less the porosity. If the moisture content is high as a result of incomplete curing, then the pores, since they already contain water, will be incapable of absorbing very much glue, and the strength must accordingly suffer.

(To be continued)

Do Furniture Makers Know How?

Faulty Veneer Work, for Which There is no Justifiable Excuse, is Prevalent, According to Retailers—Conditions Largely Remedied by Paying More Attention to Cores and Making Them up Well Before they are Needed

By S. H. Johnstone

Furniture manufacturers should find food for thought in the remark of the manager of the furniture department of one of the larger departmental stores. This was to the effect that either the furniture men of Canada did not know how to make furniture or they were taking advantage of the gullibility and ignorance of the general public for much of the furniture placed on the market was a disgrace and would not find a ready sale if the people buying furniture knew anything about it. That certainly was a strong statement and it was delivered with considerable emphasis but was not without justification. The reason in this case was some dressers which had just been placed on the floor, the tops of which resembled, I was going to say, washboards, but to say the least they were far from satisfactory.

A glance at some of the other pieces on the floor indicated that the fault was not confined to the new pieces but applied to nearly all furniture having built-up or veneered tops. There is no excuse for wavy veneered work, sunken joints or depressions of any kind. Such faults should not be permitted. If a few of the larger dealers were to adopt the policy of returning such pieces as unsatisfactory it would cause consternation in some quarters and result in a checking up of methods and more attention to results.

I don't think that any furniture manufacturer would knowingly or intentionally send out sub-standard furniture but it is a case of where the point has never been raised so that there has been no impelling reason to question either methods or results. While this may be the reason, it is not to be considered as an excuse, for every furniture maker should be proud of his product, should be willing to brand it with his name and trade mark, and should feel in honor bound to send out none but satisfactory pieces.

Why do the Faults Occur?

The faults mentioned are the result either of carelessness on the part of employees and those in authori-

(When writing mention Canadian Woodworker)

ty or the result of slipshod methods. Take sunken panels, for instance. The fault should not exist. The cause and the remedy have been outlined so often that everyone having anything to do with veneers or veneered products should know all about sunken joints. Further more, the remedy is so simple and inexpensive—simply making the cores far enough ahead to permit the glue moisture around the joints to evaporate and be distributed equally throughout the whole piece before surfacing and final sanding—that there can be no reasonable excuse for permitting this trouble to continue. If every furniture manufacturer were to make a practice of jointing and gluing core stocks well in advance, say four or five weeks or a couple of months ahead, and surface and sand the cores immediately before laying, the trouble from this source would be eliminated.

High ridges and low depressions running longitudinally of the piece result from the various pieces in the core not being of the same moisture content. This causes unequal shrinking resulting in depressions where the shrinkage was greatest. Making the cores well in advance and leaving the surfacing until the last would remedy this as well as sunken joints.

There is a tendency towards built-up instead of solid cores. This is supposed to be cheaper, as well as more satisfactory than the solid construction. This idea has not come into general use and would require some careful figuring before adopting it. It has some advantages that may recommend it. With a built-up core, by that is meant one made of thin laminations, it is doubtful if sunken joints and similar defects would be in evidence. A core of this kind would have to be put through either sander or scraper before the face material is applied.

It is well to remember that the various coats of finishing material are not applied to fill up and overly perfect the surface to be finished the less it costs to finish it and the better the results. This thought come defects or faulty workmanship. The more near- is not out of place here for more attention to the core and its preparations would go a long way toward reducing finishing costs as well as resulting in furniture in which the producer would have every reason to take pride.

Simple Idea Gives Effective Results

How Output was Increased and Saving Effected in Plant Manufacturing Veneered Doors by a Slight Re-arrangement

By P. C. Bardin

It is through unusual conditions brought about by unusual circumstances that we discover our real ability, or the lack of it. The plant cannot be found where all of the mechanical detail, the layout and the personnel meet with our entire approval. We who are strangers can walk through and observe the flaws, the faulty construction, and pick out certain individuals whom we feel could be vastly improved upon.

The people who are in daily contact with a plant are the last ones to see a fault unless it is large enough to knock them over. It is also true in many cases that circumstances force a faulty condition upon us, and while we are fully aware of the condition, we are unable to eliminate the cause. It is in such cases that we are given an opportunity to use our heads. It is in such cases that the subscription price of our trade paper is returned a thousand times by perhaps one article, one idea, or one suggestion that will prove an antidote for our particular ailment—that is, if we read our paper thoroughly.

Long Pieces Caused Trouble

The writer had occasion to go into the glue room of a millwork plant manufacturing veneer doors and interior trim along special lines. Their glue room equipment consisted of two mixers, and a vegetable glue spreader, an animal glue spreader, one hydraulic press and eight large hand presses. The work was of a decidedly special nature and very high class both in workmanship and materials used. It was necessary for the equipment as well as the men to have flexibility sufficient to meet many and varied classes of work. Everything went through either the animal or vegetable glue spreaders, from the smallest panel, perhaps twelve inches long, to panels and boards sixteen to eighteen feet long.

The necessity of running this long material was the thing that threw the figurative wrench into the machinery. In order to meet this condition it was necessary to place the spreaders in such a position so that these long pieces would not feed into the wall of the building from the out-feed end of the spreader. The hydraulic press was to the right of the spreaders due to the shape and size of the room, and hence out of the straight line of production. It was impossible to use the heavy iron building trucks and rails, which in this particular case ran at right angles to the spreader, and was necessarily too far from the outfeed end of the spreader to be of any use. On small lots and extremely special work, where quantity production was out of the question, this condition did not make one's hair raise.

It was on the larger lots of door panels for wainscot and paneled interiors where the slow process made the blood boil. The material came through the spreader and the panels were built on an ordinary factory truck. When a sufficient number of panels were laid to make a press the truck was pushed alongside of the hydraulic press and bunches of two, three or four panels were placed in the press, then a caul, then another bunch of panels, and so on until the press was full.

This press loading operation required two and generally three men to handle the panels and one man to lay cauls, and it may readily be imagined the amount of time consumed, from the time the first crossbanding received the glue until the press was released. It was always necessary to do a lot of adjusting of the panels after they were in the press due to clipping in the handling. And we must not forget the danger of defective work due to the glue drying out during the extreme length of time before pressuse was applied. We must admit that, to say the least, this was a glaring fault, and yet, looking at it from their standpoint, the arrangement of the equipment could

Simple Idea Gives Effective Results

(Continued from page 86)

not be changed, nor could the class of work responsible for the condition be eliminated.

Simple But Effective Solution

The problem was easily, quickly and effectually solved by removing the two sets of ball bearing rollers with their wooden base from the heavy iron truck (that is usually used on rails) and mounting it on an ordinary mill truck with the length of the rollers running across the width of the truck. This specially equipped truck could be run up to the spreader and panels built once and for good upon the rollers, with cauls laid and then pushed to the press and the entire load rolled into the press without any further delay or handling. Thus we see that through a simple yet effective idea it was possible to get quantity production, where the sizes and lots permitted, with the same equipment that handled the special work.

This same idea was introduced in an up-to-date panel plant where two vegetable glue spreaders were operated and only one press. The first spreader was installed in direct line with the press. However, when business necessitated another it was found that the only available space was out of the direct line, and this improvised truck proved a complete success when used in back of the second spreader.

It is not always the big things and the big ideas that help us to overcome difficulties, rather do we find the solution among the small and seemingly unimportant details. Those of you who know the business can realize the possible waste of time and money and the likelihood of defective work in the fore-going, as well as the subsequent saving made possible with a small idea and a few hours work on a mill truck. Did you ever hear of a simple yet effective invention that proved successful and then exclaim, "Why didn't I think of that?" Perhaps you can use this in your glue room. If not pass it on to the other fellow who needs it.—"The Furniture Manufacturer and Artisan."

A Course in Wood Gluing

Instructional work at the Forest Products Laboratory at Madison, Wis., is to be extended for the benefit of wood using industries other than those interested in kiln drying, boxing and crating. Starting September 11 a course in the gluing of wood will be be added.

The course in kiln drying has been given twenty-seven times, with a total attendance of 292; the course in boxing and crating has been given sixteen times, with an attendance of 143. Those taking the courses represented a large number of industries and came from all parts of the United States and even from foreign countries. Three short courses will be given in September on the kiln drying of wood from September 11 to September 22; on the gluing of wood from September 11 to September 16 and on boxing and crating on the same dates as gluing, September 11 to September 16.

In the gluing course, lasting through one week, the subjects covered will be as follows: Structure of various woods and how it affects gluing; prevention of shrinking, swelling, warping and cupping in boards or panels; effect of moisture in wood on glue joints; selection and use of animal glues, vegetable glues and water resistant glues; principles of laying veneer and plywood construction; control of temperature, pressure and assembly done in gluing; testing strength of glued joints; an analysis of defects common in gluing.

These courses are for industrial representatives and do not call for educational requirements. In offering them the purpose of the Forest Service is to help the various wood using industries to get better results with more of the lumber they manufacture or buy. In this way less timber will be needed and the benefits resulting from efficient production will be greater than those derived from the present wasteful methods.

Some of the firms who have sent representatives to the Forest Products Laboratory for a week or two of study have stated that they are able to effect savings and improve the quality of their goods to the value of thousands of dollars annually.

Conditions in Veneer and Panel Market

The Chicago Veneer Co., of Chicago, Ill., in its July review of the veneer market says:

"Building conditions are very strong, both for the present and for future requirements. The furniture and piano business has been light but the outlook is most encouraging. The stock of logs is short all over the country, which will prevent a surplus production of veneer. With these conditions and with money plentiful and confidence restored, we believe present conditions are more encouraging and more healthy than at any time during the past two years and we again predict a positive improvement, privided the mills do not take advantage of a heavy demand and consequent shortage to advance prices to such an extent that would cause another set-back. Even though we are in the midst of the vacation period and hot months, we are to-day experiencing a strong, healthy business."

The Veneer Manufacturers Co., of Chicago reports veneer conditions as follows:

"The veneer and panel industry has experienced a demand for its product far in excess of that for July months of previous years. This is due to the almost unprecedented building boom, which is not expected to lessen in activity for some months to come. Furniture manufacturers of all grades are experiencing a thriving business, which is also true of piano factories.

"The log shortage in the north, predicted in our market reports of February and March, has materialized. The mills are already far behind on orders and are finding it almost impossible to fill those on hand, due to the scarcity of logs.

"In the south—mills are working to full capacity and reports are that they have a fair supply of logs. Most of these mills are promising 30 to 60 days delivery.

"Manufacturers will do well to anticipate their needs and place orders before the coal and grain movements places an embargo on other commodities and thus avoid serious delays."

The first store to deliver goods to a customer's home rendered a service that the customer was quick to acknowledge. Now that every store gives free delivery of purchases, and so it is the expected thing, few customers pay the slightest attention to it—except when delivery is late.

C. L. WILLEY COMPANY

The Largest Veneer Plant *in the* World

THIS beautiful burl is a representative sample of several carloads of Walnut Burls recently cut and on hand at our plant ready for shipment.

With an organization world-wide in its operations you may rest assured that the type of figured veneer you want may be found at the Willey plant.

WHEN you are looking for veneer for a particularly fine piece of work—or when the "ordinary" kind will serve just as well—you will find the resources of the Willey plant a great convenience—a time and trouble saver.

When you want small lots of various kinds of veneer and hardwood lumber, your requirements can be completely met at our mammoth plant, and shipped in one lot, reducing the risk of loss and damage, and effecting a saving in freight charges.

When only one small item is desired, you have the entire Willey stock and equipment to draw from and your orders will always have our customary careful and prompt attention.

Some particularly beautiful, highly figured Walnut logs are just being manufactured—our stock is large and complete. Samples gladly sent to all who are interested.

Developments in the Use of Wood Lacquer

(Continued from page 81)

Wood lacquer will not scratch and crystallize as varnish does.

Wood lacquer resists heat that would blister any ordinary finish.

Wood lacquer will not turn white if water or other liquids are spilled on it, while varnish will.

Wood lacquer may be applied in a cold and dry atmosphere, saving the expensive installation of dry rooms and humidizing needed for varnish.

Wood lacquer will not cold-crack as varnish does.

These are a few of the good points which should be considered.

Sprayers constructed with the fluid tube inside of the air tube naturally require a higher pressure to operate than sprayers of the type in which air is discharged across the top of the fluid tube, and more rapidly syphons the material up through the container if that type of sprayer is used, and more rapidly atomizes the liquid if the overhead container or pressure supply type of sprayers are used.

A pressure not in excess of thirty-five pounds is what should be used even for a heavy wood lacquer and other materials. Some sprayers do not operate advantageously at this pressure but require a higher pressure and naturally a larger volume of air.

Since compression of air creates frictional heat, likewise expansion of air discharging through an orifice creates cold. The cold, through expansion of air, affects the finish with many solutions, and that with all solutions it causes a heavy wastage, due to the fact that with sprayers of the internal mixer type more vehicle must be used than when the type of sprayer is used which blows the air directly across the fluid tip.

This means that some sprayers are not suitable for finishing with wood lacquer, especially when using wood lacquer which must be thinned down and requires a greater number of coats, there being an undue and unnecessary amount of vehicle for the amount of actual body solution depositing and remaining on the surface of the finished article.

It would be folly to take a five-ton truck or vehicle to deliver one ton of coal, as the vehicle would depart and only leave the small amount of coal. It is just as foolish to add an undue amount of thinner to a solution, particularly wood lacquer.

The writer just received a letter from one of the lighting fixture manufacturers who was finishing his product with lacquer enamel and he complained of the work looking sandy and wanted to know the reason thereof. The answer is simple. The type of sprayer he used required high pressure and a large volume of air which semi-dried the lacquer enamel while being blown at the surface of the article and did not allow the surface to keep a saturated and wet look necessary for a smooth finish, causing a heavy wastage of vehicle and material.

Select the Right Sprayer

There are numerous sprayers on the market—presumably all of them are good for some things—to a greater or lesser extent none of them are good for all uses. The type of sprayer in which the air blows across the fluid nozzle is the most suitable for all classes of work and materials, but attention must be given to the air pressure, the volume of air and the viscosity of the solution.

One of the greatest faults which the writer has experienced among users in the past twenty-two years who have devoted themselves exclusively to this class of work, is that so many people think that because the solution must be sprayed it must be thin. The greatest drawback is to thin it. It should never be any thinner than what it would be for applying by brush, for whenever the solution is reduced that is nothing but a thinner or vehicle which conveys the body of the material to the surface to be finished, and the substance which remains after the vehicle has departed is what really gives the finished surface—the less vehicle, the less wastage.

Generally speaking, the writer would advise the use of moderately low pressure, larger air and fluid tips and a sprayer of a construction in which the air discharges below the fluid nozzles. Exception may be made for blending, shading, stenciling, etc.

Laminated Furniture Framing

There is a steadily and somewhat rapidly growing practice of making legs, posts and other framed parts of furniture out of laminated wood, where the dimensions call for something that cannot be made out of ordinary lumber stock. The high cost and the difficulties of seasoning and getting clear stock out of thick flitches has helped to increase this practice of making laminated framing parts. Another factor which has contributed to it, is the experiments of the Forest Products Laboratory which have demonstrated the qualities of laminated work and have given factory managers something official and positive to work on.

Laminated framing parts are on the whole stiffer and better from a purely mechanical standpoint than solid pieces of wood, provided, of course, that they are properly jointed and glued. About the only objection to them is that the joints show and the idea of built up work is sometimes objected to by the furniture trade on perhaps somewhat the same ground that in the earlier days they objected to veneering.

Careful matching and joining and getting similarity of texture in the wood will help to obscure the joints. And often laminated frame parts are made and pass freely as if they were solid. At other times they show very plainly. One can see in the show windows of household and office furniture stores many examples of laminated legs and posts, some made of only two pieces glued together, some three, some four and even more. And among the showings there are instances where one likes the contrasting appearance in the exposed edge of the lamination and in others it is objectionable.

On the whole, though, laminated woodwork has demonstrated its qualities and will stay with us. The final results will likely be quite a practice of building up laminated posts and frame parts, then facing them with veneer. This will furnish both the structural qualities and the face appearance and it should lead to more consistent harmony between the frame parts and the so called face parts of furnitnre.—Hardwood Record.

In most mills more oil is wasted than used. Half of this waste is caused through not scrapping old and broken oil cans. Such vessels will waste more oil in a week than would buy a new oil can.

The only prescription for sick business is the right kind of advertising.

The Latest in Kilns

(Continued from page 74)

larly efficient in producing circulation and may be used for various drying conditions.

When used as a type of external blower the kiln is connected with the blower and heater located just outside the kiln. Ducts to the drying room may be connected either with the suction or discharge side of the blower, thus permitting a reversal of air circulation.

By opening ventilators on the sides or the ceiling, circulation of air may be either through the pile horizontally or vertically. As in the use of the internal blower system, certain ventilators and baffles may be used for still more specialized types of circulation. If desired, the internal heating coil may also be used with the external system. In all cases, however, the various vents and baffles have been especially designed and fitted so that they do not interfere with the reproduction of the exact conditions of any particular type of kiln.

The control system, while effectual, is not unusual. With two reducing valves placed in series on the steam line, any desired pressure may be secured. Heating may be further regulated by using one or more of the four groups of heating coils in the kiln. Exact temperature and humidity control is possible through special devices with which any desired drying schedule is easily reproduced.

The entire kiln, though possible of so many variations of operation, is at any one time a simple, easily understood type. It is being put to work under a schedule that calls for a series of comparable runs, under various systems, to determine efficiency of drying as well as amount of heat required.

The Government's Conversion Scheme

The attention of the holders of the five and a half per cent. war loan bonds maturing December 1, 1922, is directed to the offer of the Minister of Finance to renew the loan on favorable terms. The last Canadian loan was placed in New York at a satisfactory price. The Minister is making his present financial operation entirely a domestic one by offering to exchange the maturing bonds for new bonds bearing the same rate of interest, running for either five years or ten years as the bondholder may prefer. A further inducement to the investor is that he receives a bonus of one month's interest. The terms offered are decidedly favorable to the investor and it is probable that a large part of the maturing bonds will be renewed. Arrangements for the exchange of the bonds can be made at any branch of the chartered banks. Holders who do not wish to reinvest will be paid in cash on the 1st December.

Information and Inquiries

You are cordially invited to make use of this department

Wants Veneered Slats

219 Bleury St.
Montreal, Que.

Editor "Canadian Woodworker."

Will you be good enough to advise us where we may procure a large quantity of veneered slats about 1 inch in width and in length from 4 to 10 feet? (Sample enclosed).

Yours very truly
Lavigne Window Shade Co.

The Toronto Veneer Co., 1100 Queen St. West, Toronto, are able to supply your needs and will be glad to furnish prices on application. Another firm is Robert Bury & Co., 1 Spadina Ave., Toronto. Possibly the Waterville Veneer & Panel Co., Limited, Waterville, P.Q., or any of the other firms advertising veneers in the "Canadian Woodworker" may be able to furnish the material you require.

Italian Oak Stain

11 Doulton Ave.
London, Ont.

Editor, "Canadian Woodworker."

The "Canadian Woodworker" for February contained an article by W. H. Dawson on finishing oak and using Italian oak stain. Can you inform me where I may obtain the Italian Oak Stain powder mentioned in the article?

Thanking you, I am
Yours respectfully,
A. Jenson.

If you like, you can write Mr. Dawson direct, c/o Celluloid Zapon Co., Wilmington, Deleware, with regard to the Italian Oak stain mentioned is his article. It is possible, however, that any of the manufacturers of finishing material advertising in the "Canadian Woodworker," would supply you with an Italian oak stain that would suit your requirements.

Information on Oak Flooring

Seaforth, Ont.

Editor, "Canadian Woodworker."

Could you give me the name of one or two firms who manufacture oak flooring as a specialty and could you also give me any information about laying and finishing oak flooring, or suggest a book on the subject . We should be much obliged for any information.

Yours truly,
Wm. G. L. Edmunds.

If you write the Seaman, Kent Co., Limited, Wallace Ave., Toronto, they will give you full information covering the cost of laying and the finishing of hardwood floors. We are under the impression that they issue a booklet covering the laying and finishing of such floors.

Green Cast on Mahogany

Editor, "Canadian Woodworker."

In the finishing of a number of our mahogany phonograph cabinets we have been troubled with an undesirable greenish cast. We use spraying equipment and are wondering if there is anything in the way we handle the machine that might cause this green shade. Will you kindly advise us if spraying equipment can be mishandled in this way?

Yours very truly,
P. C.

We have submitted your inquiry to the DeVilbiss Mfg. Co., Toledo, Ohio, manufacturers of spray equipment, and they reply as follows:— "There is nothing in the spraying method of application that should produce the discoloration on the work referred to in your inquiry. This kind of work is being done right along by furniture manufacturers. There are many things that might be responsible but it is difficult to tell without careful investigation of the work. Our finisher advances the suggestion, however, that the customer may be using a shellac with a rossin gum, putting some turps in it for binder which would likely cause the trouble you speak of. Then again, they may be using gasoline or a similar light solvent in their filler. This would have a tendency to produce a grey or a greenish cast.

Hardwood Handles for Can Openers

Metapedia, P. Q.

Editor, "Canadian Woodworker."

Could you give me the names and addresses of any manufacturers of hardwood handles? I require a lot of handles for can-openers, about 5 inches long and 3/4 inch in diameter.

Yours truly,
James Kenny.

The Canada Wood Specialty Co., Limited, Orillia, Ont., could take care of your requirements for hardwood handles.

Makers of Mouldings

24 Hager Ave
Toronto, Ont.

Editor, "Canadian Woodworker."

Would you please inform me of the address of a firm in the city who make cabinet makers' mouldings in oak, walnut, etc., or who make a practice of running mouldings to order.

Yours truly
Wm. Graham.

We do not know of any firm specializing in the running of detailed mouldings but believe that such firms as the Builders' Moulding Supply Co., Noble St.; George Rathbone & Co., Quebec Ave., or the R. Laidlaw Lumber Co., 2268 Dundas St. West, will be pleased to take care of your requirements in moulding.

Editor, "Canadian Woodworker."

The following table of discounts and equivalent interest rates appeared on page 96 of your June issue:

½% 10 days—net 30 days is equal to 9% interest per annum
1 % 10 days—net 30 days is equal to 18% interest per annum
1½% 10 days—net 30 days is equal to 27% interest per annum
2 % 10 days—net 60 days is equal to 14% interest uer annum
2 % 10 days—net 30 days is equal to 36% interest per annum
½% 10 days —net 30 days is equal to 9% interest

Will you please let me have a memo, showing how these figures are calculated.

Yours truly
N. M.

To illustrate the way in which these discounts

Uniform Lumber Means Greatest Satisfaction To The User!

You no doubt have experienced the expense, loss of time, and loss of materials, caused by the use of improperly cured, wrongly graded, and carelessly handled hardwood.

Kraetzer-Cured Lumber is absolutely uniform in quality, properly graded, and every board plainly marked, showing the grade. To show our faith in Kraetzer-Cured products, every board is stamped with our brand.

THE KRAETZER-CURED LUMBER CO.

Because of our unusual facilities we control the lumber from the virgin growth to the time it is loaded on the cars and shipped to you.

When you have once used Kraetzer-Cured Lumber you will not be satisfied with the ordinary kind. Read the eight important reasons why Kraetzer-Cured Gum is used by thousands with such satisfactory results. It will give the same results to you.

Kraetzer-Cured Lumber is of the very best quality, carefully handled by all departments. Every step in this process is taken with the idea of producing uniform high grade hardwood that w ill give maximum service in your hands.

In addition to Kraetzer-Cured Gum, we can furnish Oak, Ash and other Southern Hardwoods.

The Kraetzer-Cured Lumber Co.

GENERAL OFFICE: GREENWOOD, MISS.

Band Mills: Greenwood, Miss., Moorehead, Miss. Leflore, Miss.

You Should Use KRAETZER-CURED GUMWOOD *Because:-*

1. It is STRAIGHT and FLAT, free from the warp and twist usually encountered in untreated stock.
2. It is BRIGHT and will satisfactorily take any finish.
3. It is free from dote or rot—the sap and gums are eliminated by the steaming process, and fermentation and decomposition are thus prevented.
4. Through the elimination of stain and decomposition, it possesses greater strength and longer life.
5. It contains only atmospheric moisture, enabling it to be used for many purposes without kiln drying.
6. When kiln drying is necessary, this can be done in much less time and with more satisfactory results.
7. It is uniform and dependable. One car like another, grade and measurement what it should be—no time w a s t e d in reporting complaints or shortages, no delays or interference with factory schedules because of holding lumber for adjustments.
8. It is the most economical lumber available. It will satisfactorily answer any requirements expected of materially higher priced woods.

Join our little army of satisfied users, and just as peace is about to supplant war, let peace of mind take the place of the warfare and worries that usually beset the user of lumber.

We're proud of this product —that's why.

rates work out, we shall take the second item in the list; that is 1% 10 days; net 30 days, which is equal to 18% per annum. The manner in which this is worked out is as follows:— The bill is not due for 30 days but if you pay it in 10 days you are allowed a discount of 1% which means a 1% saving for 20 days, which is tquivalent to an 18% saving for 365 days or a year; in other words, by discounting the bill 20 days before it is due, you have saved at the rate of 18% per annum. To follow out this reasoning, take the fourth item on the list, viz., 2% in 10 days; net 60 days. In this case you save 2% in 50 days, which works out to 14% for a year.

The Lumber Market

Domestic Woods

In the hardwood lumber line business is showing some evidence of a revival, and becoming more settled. A very satisfactory trade is being looked forward to by a number of industrial concerns this fall owing to the excellent harvest at home and in Western Canada. Agricultural implement works will soon resume on a fairly large scale, furniture plants are expected to get busier and piano factories will also be sharing in the recovery. There has been quite a call for 4/4 No. 2 common and better ash for kitchen cabinets, refrigerators and other lines. The thick and better grades of birch and maple are moving a little more freely and more inquiries are beginning to come in. No. 1 common and better in birch from 6/4 up to 10/4 is selling well, while maple in 5/4 and 6/4 No. 2 common and better, is showing more evidence of life

There is no doubt, however, that any improvement has been somewhat halted during the last few days through the railway strikes, the acute coal situation and other disturbing factors.

All sales of Canadian hardwoods are made principally across the border, Canadian requisitions being limited as the majority of consumers have large stocks on hand at present and are not disposed to load up with any additional material.

Producers of Canadian hardwoods find it extremely difficult to get rid of their low ends. In some cases these connot be disposed of at a sacrifice and there is in consequence little or no profit for the operator. Speaking of this state of affairs, a leading exponent of the trade stated recently that, in the average run of logs, about 50% of the lumber was No. 2 and No. 3 common. He classified the output as follows:—

20% 1sts. and 2nds. 30% No. 1 common and better. 20% No. 2 common. 30% No. 3 common.

At to-day's prices there cannot be obtained on the average more than $8.00 for No. 3 common; $20.00 for No. 2 common; $45.00 for No. 1 common and better and $85.00 for 1sts and 2nds. This makes the average for log run about $37.00 and $38.00 and no one, who gives any consideration to the present cost of carrying lumber, will for one moment maintain that the producer can make a profit at present figures. There is too much low-grade lumber, which commands no ready market. The speaker said that it would cost, at least, $10.00 per M for sawing, piling and loading the lumber, and on top of this must come the outlay for woods operation, driving or hauling the logs, loss in transit, etc. Then to carry the stock costs, at least, 2% a month when bank interest, insurance rates and depreciation are taken in consideration.

Imported Woods

The main element affecting the hardwood market in the United States at the present time is the labor situation, the movement of lumber being restricted quite considerably and buyers holding off pending a settlement of the trouble. It is expected that when the strike situation clears up, the market will improve, although even at the present time many of the mills claim business is quite satisfactory with sales holding their own in spite of adverse conditions. In many centres inquiries for both quick and long shipments are growing, indicating that some improvement in the situation may be expected in the course of the next month or so. Prices in general are holding firm at the levels which have prevailed for several weeks, whatever fluctuations that have taken place being only minor in extent. The building situation throughout the States seems quite spirited, and to satisfy the needs of construction, much lumber is being marketed. Builders anticipate continued activity during the remainder of the season, so that lumbermen expect continued sales in this line.

Memphis, Tenn.—At this point, as in other lumber centres throughout the United States, a shortage of cars and congestion of freight incident upon the national railroad strike, is causing shipments of hardwood lumber to be withheld. It is reported that some of the mills have been forced to close down owing to lack of logs, while others are operating at only a percentage of capacity. Outgoing shipments are likewise restricted. Much concern is also felt about the lumber situation, in view of the approach of the crop-moving period which will inflict another hardship on the lumber interests. The demand for Southern hardwoods seems very good and stocks of No. 1 common and better are below normal. An increase is reported in the sale of low-grade lumber especially Nos. 2 and 3 common, with prices somewhat improved. The largest demand is from manufacturers of flooring, planing mill products, automobiles, furniture and crating.

Louisville, Ky.—The movement of logs to the mills is restricted owing to the car shortage. However, a fair demand for most woods is reported with the flooring trade and the trim producers pretty well in the lead. Building operations are very heavy. Not much buying is done on the part of the furniture trade.

Evansville, Ind.—Trade here is not expected to be like normal until the strikes are settled. Lumber manufacturers report quite a falling off in trade although orders and inquiries continue to come in. Improvement is expected by the first or middle of September. Furniture manufacturers and others engaged in the woodworking industry state that the situation depends now on a settlement of the railroad and coal strikes and that business will be satisfactory when these difficulties have been cleared up.

The cabinet maker who is very economical in the matter of clamps should not be surprised if he hears a good many complaints about his work.

News of the Trade

Manual training equipment will shortly be installed in the Oakville, Ont., high school. ,

Fire caused $1,000 damage recently to Mr. Sargent's planing mill on King St., London, Ont.

The Globe Furniture Co., Waterloo, Ont., is erecting an addition to its factory, at a cost of $15,000.

Linde Canadian Refrigerator Co., Lachine, Que., are building a new factory at a cost of $40,000.

Mr. Nathan Calder is building a planing mill on Inkerman St., Listowel, Ont., and is interested in the prices of equipment.

Announcement was made recently by Robert Gray that Gray-Dort Motors, Ltd., will erect a large plant at Windsor, Ont.

The lumber mill of Albert Parsons, Walton, Hants County, N. S., was completely destroyed by fire with a loss of about $10,000.

The millwork contract on the new Catholic school at Bordeaux, P. Q., was recently awarded to Mr. George Lebel, 201 Baby St., Montreal.

William Luck, Holland Landing, Ont., for many years engaged in the carriage making business, passed away recently in his 89th year.

Purdy Radio Phonograph Co. Ltd., Toronto, was recently incorporated to manufacture and deal in radio and phonograph equipment. Capital $40,000.

The Gotfredson Joyce Corporation, Ltd., Walkerville, Ont., truck manufacturers, have awarded a contract for an addition to their factory to cost $40,000.

The Whistle Bottling Company of Hamilton, Ltd., Hamilton Ont., has been incorporated to manufacture and sell all kinds of containers including wooden boxes.

R. Truax & Co., Walkerton, Ont., are excavating for the construction of a dam to furnish power for their sash and door factory on the Saugeen River.

The Canadian Top & Body Co., Tilbury, Ont., held a picnic at Seacliff Park, Leamington, Ont., recently, when seven hundred people enjoyed the day.

Drapery Trimmings, Limited, Toronto, were recently granted a provincial charter to manufacture and market upholstery trimmings, braids, laces, tassels, etc. Capital $50,000.

The Hayes Wheel Company of Canada, Ltd, Chatham, Ont., have been granted a federal charter to manufacture carriages, wagons, automobile bodies, trucks and all kinds of wooden wheels, with a capital of $1,800,000.

Shea's Hippodrome, Toronto, will shortly install a $40,000 pipe organ. When the Hippodrome was opened in 1913, an orchestral organ was purchased in Germany, but the instrument proved too mechanical and was abandoned.

Jean L. Auger, St. Mathieu, Que., is putting in the foundations for his new planing mill. The building when completed will be a one and a half storey structure and will cost about $6,000.

Dodge Bros., automobile manufacturers of Detroit, Mich., have purchased a factory site in Windsor, Ont., and will erect a large plant there to look after Canadian and possibly their export trade.

The Queen City Furniture Co., Toronto, recently added 4,000 square feet to their factory, giving them a total of 46,000 sq. ft. The company also found it necessary to double their staff.

S. C. Johnson & Son Company, varnish manufacturers of Brantford, Ont., announce they will build an addition to their plant at a cost of $125,000. If the plans materialize, Brantford will have one of the largest manufacturing plants of this kind in Canada.

Messrs. A. E. Smith & Son, of Cataraqui, Ont., recently opened a woodworking plant and are manufacturing ironing tables, clothes racks, medicine chests and cabinet work of every description. The company hopes to extend their premises and install additional machinery in the near future.

Messrs. J. P. Abel Fortin & Co., 383 Desjardins St., Montreal, were recently awarded the contract for millwork on the new Stadacona School, for the Catholic School Commission, being erected on Stadacona street, between Darling and Davidson streets.

Damage estimated at $25,000 was caused by fire recently at the plant of Messrs. Germaine Lepine Co., undertakers and coffin manufacturers, St. Valier St., Quebec. Thirty thousand feet of fine boards were destroyed, along with several vehicles which were in storage.

A. Chown & Co. Ltd., Kingston, Ont., have been incorporated to take over the business of A. Chown & Company, and to manufacture and deal in heavy hardware for carriages, automobiles, boats, etc. Capital $200,000. A. F. Chown and P. B. Chown are two of the incorporators.

The millwork contract on the new school at Mountain & Parr streets, Winnipeg, Man., is held by Messrs. Brown & Rutherford and Messrs. Sutherland & Buchanan. These two firms also share the millwork contract on the new school at Grosvenor Ave. and Wilton St., in that city.

The British & Colonial Furniture Co., Ltd., Toronto, have been granted a provincial charter to manufacture and deal in furniture and fixtures, provided they do not use more than $100,000 capital in Ontario. Colin J. Lappin, of Toronto, is manager of the new company.

Joseph Landreville & Sons, Ltd., Toronto, Ont., were recently granted a provincial charter to manufacture and market all kinds of cooperage stock. Capital $100,000. J. D. Landreville and J. C. Landreville, both of Toronto, are two of the incorporators.

The "1900" Washer Company, Binghampton, N. Y., makers of washing machines, are negotiating with Beatty Bros., of Toronto, to sell their Toronto branch, which is largely an assembling plant. Beatty Bros. will, if the plans carry, erect their own production plant and employ a large sales staff.

Wm. Black, of the Yorkton Planing Mill, (Logan & Black), Yorkton, Sask., died recently in the local hospital, following an operation for appendicitis. Mr Black was well known throughout the district having been connected with the above firm for a period of 17 years.

The Sault Lumber & Mill Co., Sault Ste. Marie, Ont., was recently granted a charter, with a capital of $125,000. and is the successor to the Corrigan Lumber & Mill Co. F. E. Hollingsworth is president and manager of the new company.

The Sterling Woodworking Company were recently awarded the millwork contract for the new Medical Arts building, at the corner of Guy and Sherbrooke Streets, Montreal. Their address is care of the architects, Messrs. Ross & MacDonald, 1 Belmont St., Montreal.

The late Dr. Alexander Graham Bell, the inventor of the telephone who passed away at his estate Beinn Bhreagh, near Baddeck, N. S., recently, was a builder of high class boats. During the war Dr. Bell did useful work in building small craft for the Canadian and British governments. It was the first boat building establishment to employ women.

Mr. Alfred J. Paro, Trenton, Ont., recently constructed a fine sash and door factory in that town. The factory is equipped with modern machinery for the manufacture of sash, doors, frames, trim turning and cabinet work of all

kinds. Although the factory has been under way but a short time, Mr. Paro reports plenty of business on hand.

The Art Craft Furniture Co., Goderich, Ont., a new concern recently organized, has been granted exemption from taxation except school and business tax, for a term of years. The ratepayers also authorized the sale of the factory formerly owned by the Wheelrigs to the new furniture company for $9,700, the amount owing by the former company.

Dauncey & Nelson, Brighton, Ont., sash and door and interior trim manufacturers, recently dissolved partnership, the interest of the latter partner being purchased by J. Carther. The firm is now known as Dauncey & Carther Lumber Co. Business is reported by them to be very satisfactory this season.

The question of most vital interest, however, is whether or not the period of greatest stress is behind us. A decreasing total of failures in the United States duirng the successive months of the present year would seem to indicate a definite improvement in conditions. Canadian figures disclose a similar situation, in spite of the extremely high business mortality rate during the first half of the year. The record of solvency during the second quarter is an improvement over that of the first quarter.—Royal Bank of Canada.

The sash and door plant of S. L. Lambert, Welland, Ont., was totally destroyed by fire lately, entailing a loss of $30,000. The building destroyed was a structure, 30 x 110 ft., with some of the machinery still in the process of installation, including a $4,000 piece of equipment which had worked but three loads of lumber. The insurance is about one-third of the total loss.

The Clatworthy Lumber Co., Limited, with head office in London, Ont., and a capital stock of $40,000., has been granted a provincial charter, to carry on a business dealing in wood and coal, as well as timber merchants, sawmill and planing mill operators, etc. The incorporators are A. J. Clatworthy, of Granton, Ont., and T. A. Clatworthy and M. F. Clatworthy, of London.

Mr. R. H. Tye recently purchased the interest of J. C. Scripture, of Colborne, Ont., in a fine planing mill and lumber business in that town. The planing mill is equipped with modern machinery throughout and has an excellent location. There is a saw mill at the rear of the planing mill and the yard is well stocked with lumber. Business is reported very good.

Mr. F. A. Hubbs, of Picton, Ont., a well known figure in the woodworking trade throughout, Ontario, recently opened a sash and door factory in the above town. Mr. Hubbs was for several years connected with A. H. Brown in the woodworking business, later head of the firm of Hubbs & Allen, manufacturing sash and doors, and was foreman of the sash and door factory of Hayatt & Hart until this company was burnt out.

The Bell Furniture Co., Limited, of Southampton, Ont., are adding four more Class D, Sidman lumber curing kilns in concrete buildings to their battery of kilns. They are also completing their storage sheds, transfer and kiln car yard system, and when completed all their lumber will be piled direct from the railroad cars onto kiln cars, the lumber being handled only once from the railroad cars to cut-up saws.

The plant of the Dominion Furniture Company, Edmonton, Alta., was completely destroyed by fire recently. The loss is estimated at about $40,000, not a piece of furniture or machinery being saved. The company was organized a little over a year ago and their product, manufactured from native woods and treated with a curing process, was finding a ready market in Western Canada. R. H. Douglas is the present manager of the company.

The Art Craft Furniture Company, Goderich, is a new firm recently organized. H. N. Ubelacker, of Stratford, is the managing director and R. P. Gough, president of Sellers-Gough, and Hon. T. W. McGarry, formerly provincial treasurer of the province of Ontario, are included in the directors. The new company will be established in the large plant formerly occupied by the Goderich Merchantile Co., with the city of Stratford in view for future developments. Between 55 and 60 hands will be employed at the outset.

The Satin Finish Hardwood Flooring Co. Limited, has been granted a charter and has installed a plant in the former K. & S. tire factory in Weston, Ont. The authorized capital of the company is $100,000. and the organization is empowered to carry on the business of manufacturing and dealing in hardwood flooring, sash, doors, woodenware, etc. Among those associated with the enterprise are W. C. Gardiner, late of the Builders' Moulding Co., and W. T. Cole, late of the Seaman, Kent Co., Toronto.

Obituary

William Simpson, who for many years was at the head of the William Simpson Planing Mill, Queen St. West, Toronto, died recently at his home. He had resided in Toronto for 45 years, but retired from business in 1905. Mr. Simpson was born in Keith, Scotland, 80 years ago and came to Canada when a young man, entering the lumber line. He is survived by his widow, four sons and four daughters.

Harry K. Bowes, M.A., managing director of the Office Furniture & Supplies Company, Brockville, Ont., died at his residence in that city recently after an illness of some duration. Deceased was 39 years of age, a native of Sackville, N. B., and a former resident of Ottawa. Deceased was a member of the local Board of Education and president of the Young Libera Club.

Face to Face With Prosperity

Winnipeg, August 8.—Grain companies, mills, railroads and the Lake Shippers' Association are just now feverishly preparing to handle what is expected to be the largest grain yield in the history of the Canadian Northwest. Rolling stock is being borrowed from eastern divisions and the banks are accumulating surpluses of cash at small branches from the lakes to the mountains in preparation for the big movement.

Official statistics from the grain exchange show the wheat acreage of the three provinces to be 21,146,000. In 1915 the acreage was 13,867,715. The average yield per acre then was 25.97 producing a yield of 360,187,000 bushels. The most optimistic, however, does not anticipate a yield so high this year. For ten years, however, the average has been 17 bushels. Upon this basis the yield this year would be 359,822,000 and this is the minimum that well informed sources expect will be produced.

The question on October wheat, say July 10, 1915, $1.03⅜. July 10 this year October wheat quotation was $1.16¼. On the basis of this quotation this year's crop ought to yield at Ft. William, $417,393,520 or in cash, $47,250,000 more than the famous 1915 crop. The amount that would reach the farmers' hands would be, in cash, $327,438,000 because it costs 18 cents freight and six cents elevator charges per bushel to handle to head of the lakes. Approximately this amount of cash will be released through ordinary business channels in the west this fall.

Of course this is a debt-paying crop, but if conditions today continue it means that the books will be cleaned and all paper liquidated.

One capable of getting out drawings and taking off bills of material necessary, and thoroughly experienced in the handling of men. State age, experience, salary and references. Box 139 Canadian Woodworker, Toronto. 8

Grant Permit to Develop Power at Kettle Falls on Columbia

The U. S. Federal Power Commission has authorized the issuance of a preliminary permit for three years to the Washington Water Power Co. for a power project at Kettle Falls on the Columbia River. The ultimate installation is estimated at 153,400 h.p. The company proposes to develop the project in three stages correspondingly as a market for the power can be found. In the initial development it is proposed to use the natural fall of about 30 ft. at Kettle Falls. As the demand for power increases, additional capacity will be provided by building a 60-ft. dam across the Columbia River. The height of the dam may later be raised to 75 ft. by the use of gates. Provision is made in the permit for the conveyance to the United States of such lands and rights-of-way as may be required for navigation facilities built by the United States.

Under a treaty With Great Britain made in 1846, the Columbia River is to be kept open for navigation by British subjects trading with the Hudson Bay Co. The permit provides that project works shall be designed to keep existing portages free and open.

Belgian Production of Iron and Steel in May

Figures of Belgium's iron and steel output for May show pig-iron production to have regained the March level after a sharp decline in April, reaching 118,940 tons. Raw steel, with a May production figure of 112,610 tons, also shows a marked improvement over preceding months, being 186 per cent. of the average monthly output during 1921.

Owing mainly to French competition, rough steel castings declined to 5,690 tons, this figure being lower than for either of the months immediately preceding. Finished steels, however, advanced to 102,030 tons in May, an increase of 10 per cent. over April. The finished-iron output amounted to 12,320 tons, an advance of 75 per cent. over the April figures.

Smelter production for May was 8,830 tons, slightly superior to April but not attaining the maximum reached in March.

Allotments for Tokyo Improvements

A special committee has studied the allotment funds for the improvement of the streets and canals in Tokyo at the request of the Home Minister. They came to the conclusion that a total sum of $54,500,000 should be allotted for these purposes and spread the work over seven years. Of this amount there is allotted for street improvement 10 per cent. of the total during 1922, 15 per cent. in 1923, 15 per cent. in 1924, 16 per cent. in 1925, 18 per cent. in 1926, 17 per cent. in 1927, and 9 per cent. in 1928; while for canal improvements 20 per cent. of the total is allotted for 1922, 21 per cent. for 1923, 17 per cent. for 1924, 17 per cent. for 1925 6 per cen. for 1926, 13 per cent. for 1927, and 6 per cent. for 1928. It would appear that this program would justify the employment of important amounts of construction machinery.

"Pony" Cabinet Clamp

For lightness combined with strength this clamp has no equal. All parts are selected from the best materials obtainable and we have spared no effort to make the "Pony" the finest thing of its kind on the market. Made in sizes to open 18 in. to 72 in.

A Small Article
of Great Importance

Realizing the importance of efficient casters, we have made a specialty of this line and as proof of their quality we need only say that many of the foremost furniture manufacturers are using them exclusively.

By the way don't it seem logical that a Canadian-made caster should be the right one to use on Canadian-made furniture? Assuming of course, that it equals the standard of the imported article?

If you believe so too, just write us for samples and prices.

To Holders of Five Year 5½ per cent Canada's Victory Bonds

Issued in 1917 and Maturing 1st December, 1922.

CONVERSION PROPOSALS

THE MINISTER OF FINANCE offers to holders of these bonds who desire to continue their investment in Dominion of Canada securities the privilege of exchanging the maturing bonds for new bonds bearing 5½ per cent interest, payable half yearly, of either of the following classes:—

(a) Five year bonds, dated 1st November 1922, to mature 1st November, 1927.

(b) Ten year bonds, dated 1st November, 1922, to mature 1st November, 1932.

While the maturing bonds will carry interest to 1st December, 1922, the new bonds will commence to earn interest from 1st November, 1922, GIVING A BONUS OF A FULL MONTH'S INTEREST TO THOSE AVAILING THEMSELVES OF THE CONVERSION PRIVILEGE.

This offer is made to holders of the maturing bonds and is not open to other investors. The bonds to be issued under this proposal will be substantially of the same character as those which are maturing, except that the exemption from taxation does not apply to the new issue.

Holders of the maturing bonds who wish to avail themselves of this conversion privilege should take their bonds AS EARLY AS POSSIBLE, BUT NOT LATER THAN SEPTEMBER 30th, to a Branch of any Chartered Bank in Canada and receive in exchange an official receipt for the bonds surrendered, containing an undertaking to deliver the corresponding bonds of the new issue.

Holders of maturing fully registered bonds, interest payable by cheque from Ottawa, will receive their December 1 interest cheque as usual. Holders of coupon bonds will detach and retain the last unmatured coupon before surrendering the bond itself for conversion purposes.

The surrendered bonds will be forwarded by banks to the Minister of Finance at Ottawa where they will be exchanged for bonds of the new issue, in fully registered, or coupon registered or coupon bearer form carrying interest payable 1st May and 1st November of each year of the duration of the loan, the first interest payment accruing and payable 1st May, 1923. Bonds of the new issue will be sent to the banks for delivery immediately after the receipt of the surrendered bonds.

The bonds of the maturing issue which are not converted under this proposal will be paid off in cash on the 1st December, 1922.

W. S. FIELDING,
Minister of Finance.

Dated at Ottawa, 8th August, 1922.

The Load You Can't Estimate

NO matter how great is the foresight of the machine designer, he cannot guard against unexpected thrust loads on the bearings caused by conditions beyond his control.

The Deep Groove Bearing can withstand thrust loads greatly in excess of its radial capacity and coming from either direction.

Both the design and quality of this double purpose bearing are endorsed by the mark **SKF** and are backed by the world-wide researches and long experience of **SKF** Industries.

This experience is at your disposal and you are urged to submit your bearing problems to us for free and impartial advice.

CANADIAN **SKF** COMPANY, LIMITED

Now They Do a Better Job of Sanding Mahogany Veneers—

IT wasn't so very long ago that the men on the sanders in a certain plant began using Carborundum Brand Garnet Belts in No. 1 grit on sanding thousands of fine mahogany veneer panels.

They had been going on the theory that garnet belts were just garnet belts and that one make was about as good as another until—

They began using belts they cut from Carborundum Brand Garnet Cloth.

Then it wasn't long before they realized that there was a difference. Now they have belts that cut speedier, cleaner, more uniformly—belts that are true and even, belts that produce more work—better work.

CARBORUNDUM BRAND GARNET PRODUCTS ALWAYS MAKE GOOD SANDERS BETTER SANDERS

The Carborundum Company, Niagara Falls, New York

BOOKS FOR SALE

The following books are offered at special prices subject to previous sale :

"Machine Molder Practice," recently published by the Practical Books Co. 172 pages, 100 illustrations. Flexible leather binding. Price $3.00.

"The Utilisation of Wood-Waste," by Ernest Hubbard, Third English revised and enlarged edition, 236 pages, illustrated. Published in 1920 by Scott, Greenwood & Son. Price $2.00.

"Modern Practical Joinery,"—A comprehensive treatise on the practice of joiner's work by hand and machine. For the use of Workmen, Builders, Machinists and Architects. Containing a full description of drawing instruments and their use; tools, appliances and apparatus; methods and processes; joints and fastenings; woodworking machines; machine shop practice; preparation of work for machining; use of the steel square; house joinery, bank, office, church, museum, domestic and shop fittings, show cases, air-tight cases, splayed and shaped work; new materials and method, stairbuilding, foremen's work, fixing, and a description of nearly 150 woods suitable for joinery. Together with a comprehensive glossary and index. By George Ellis—fourth edition, extensively revised and much enlarged. With upwards of 1400 illustrations, including 20 double page and 41 photographic plates. Recently published by B. T. Batsford Limited, 570 pages Price $12.50.

"The Kiln Drying of Lumber," a Practical and Theoretical Treatise, by Harry Donald Tiemann, M.E., M.F. Just published, by J B. Lippincott Co. 316 pages, illustrated. Price $5.00.

Seasoning of Wood; A Treatise of the Natural and Artificial Processes Employed in the Preparation of Lumber for Manufacture, with Detailed Explanations of its Uses, Characteristics and Properties, by Joseph Wagner. Published by D. Van Nostrand Co., in 1917. 274 pages, illustrated. Price $3.00.

"Modern Practical Carpentry"—For the use of Workmen, Builders, Architects and Engineers. Containing a full description of the methods of constructing and erecting roofs, floors partitions, scaffolding, shoring, centering stands and stages, coffer dams, foundations, bridges, gates, tunnels excavations, woods and half timber houses and various structural details. Together with new and simple methods of finding the bevels in roofs, setting out domes, steeples, etc. An account of failures in construction, and the theory of trussing frames. Also including a concise treatise upon timber; notes on the woods used in carpentry; various tables; a glossary of terms and phrases connected with carpentry; and a chapter on the uses of the steel square. With about 1100 illustrations. By George Ellis—second edition revised. Recently published by B. T Batsford Limited, 396 pages,—price $7.50.

Morgan No. 6 Nailing Machine

MORGAN
NAILING MACHINES
Used in Nailing Wooden Toys

Many manufacturers of American Wooden Toys use our machines for driving 5/8" to 1 1/8" nails. Machines are adjustable in operation and can be adapted to any kind of nailing work.

If you are driving nails by hand, in making boxes, crates, toys, any woodenware articles, figure the cost. It is expensive.

Then send us samples of your work. Get an estimate of the cost of nailing on a Morgan Nailing Machine. Compare the figures. We'll leave the rest to your judgment.

Send us your nailing problems. We shall be pleased to give them our careful consideration and advise you regarding equipment for handling them. We invite your inquiry.

Morgan Machine Company
Rochester, N. Y.

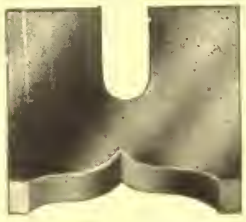
ATKINS

STERLING QUALITY

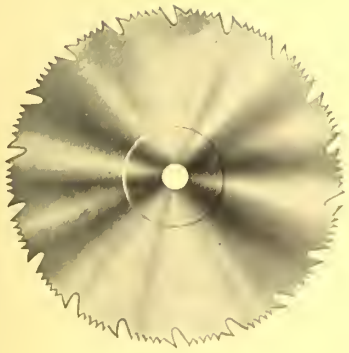
SAWS and KNIVES ECONOMIZE



ARE your saws and knives wasting your lumber? If so, why not turn that waste into a profit by installing

Atkins Sterling Quality Saws

and Machine Knives



Some of the largest woodworking mills in the country are using Atkins Saws exclusively, because they increase production, stop waste and make a name for themselves wherever they go.

Write to-day for our Knife Booklet "C.W." and Pattern Template Paper.

E.C. ATKINS & CO.

Makers of Sterling Saws

Factory—HAMILTON, Ont. **Vancouver Branch—109 Powell Street**

Our double-end drive with adjusting, tensioning and take-up devices, positively prevents any slap or lost motion at end of stroke.

In place of the old-fashioned stranded wire cable, we employ a tempered steel driving band which cannot wear or stretch.

Automatic Sander Produces a Perfect Finish

RIGID, heavy construction, high-grade ball bearings, efficient tensioning devices and expert workmanship throughout, combine to impart an exceptional sensitiveness to the operating control. This feature, together with the flexible mounting of the sanding pad and the uniformity of stroke, produces a faultless finish with no streaks or waves to show up through the varnish.

Through the combination of power stroke and hand control, the operator is enabled to manipulate the pressure shoe to suit each individual job, eliminating spoilage, increasing capacity and obtaining a finish so perfect that to further touch it by hand would spoil it.
Ask us for further evidence of its superiority.

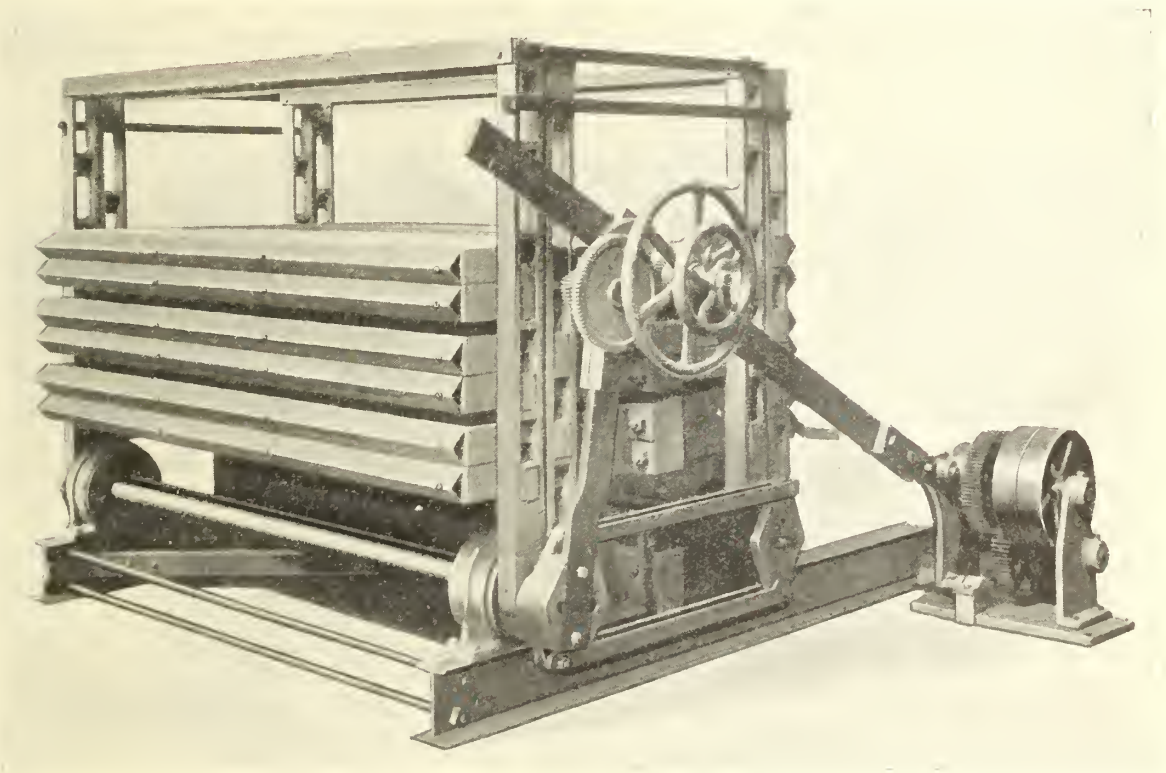
Shrinkage How it Affects Veneer



Take ordinary air dried veneer. It contains anywhere from 8% to 15% moisture. It is as dry as the air but no drier.

It is then passed through the glue spreader. Immediately it absorbs additional moisture and consequently contains more moisture than does the air.

After a time your glued up panel suffers as a result. The air being drier than the panel, the veneer begins to dry out and to shrink gradually. Open joints and fine checks appear; blisters occur; warping takes place and often the panel must be replaced.

How different when veneer is re-dried by the Perrin Veneer Re-Drier. Hot plates, steam heated, draw out the moisture left in by the air-drying process. The veneer becomes drier than the air so that even after it has been through the glue spreader, it still contains no more than the normal amount of moisture. Veneer applied after being Perrin re-dried makes a permanent job. No after-troubles occur.

Are your panels going out in the proper condition?

The Perrin Veneer Re-Drier is simple to operate. It is suitable for any plant and its capacity can be increased as occasion demands. Why not ask us for fuller particulars.

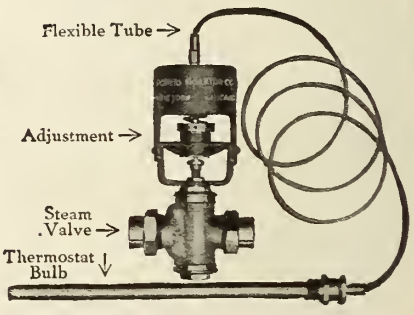
DRY KILN
Better Drying in half the time

Controlling Heat For Industry

Powers Regulation, installed on any system of artifical heat, insures economy, safety, and the correct temperature.

Regardless of the kind of temperature to be controlled—whether of liquid or air —or for what purpose—there is a Powers Regulator specially adapted to that purpose—for controlling the temperature of a single room or an entire building—for vats—ovens—dryers—dyers—kilns —glue pots—varnish rooms—and many other places where heat control is necessary for best results.



The Powers Regulator No. 11

Specially adapted for the control of liquid temperatures as in hot water tanks, acid baths, glue pots, dye kettles, etc. Entirely automatic and self-contained, requiring no outside power for operation. Send for Bulletin 129. Other designs for other uses, wherever heat control is desirable.

Powers Regulators save time, conserve energy, protect material in process of manufacture. They are automatic, dependable, accurate.

Powers Regulation is the result of more than 30 years of labor in this one field. Let us help you in meeting today's manufacturing problems.

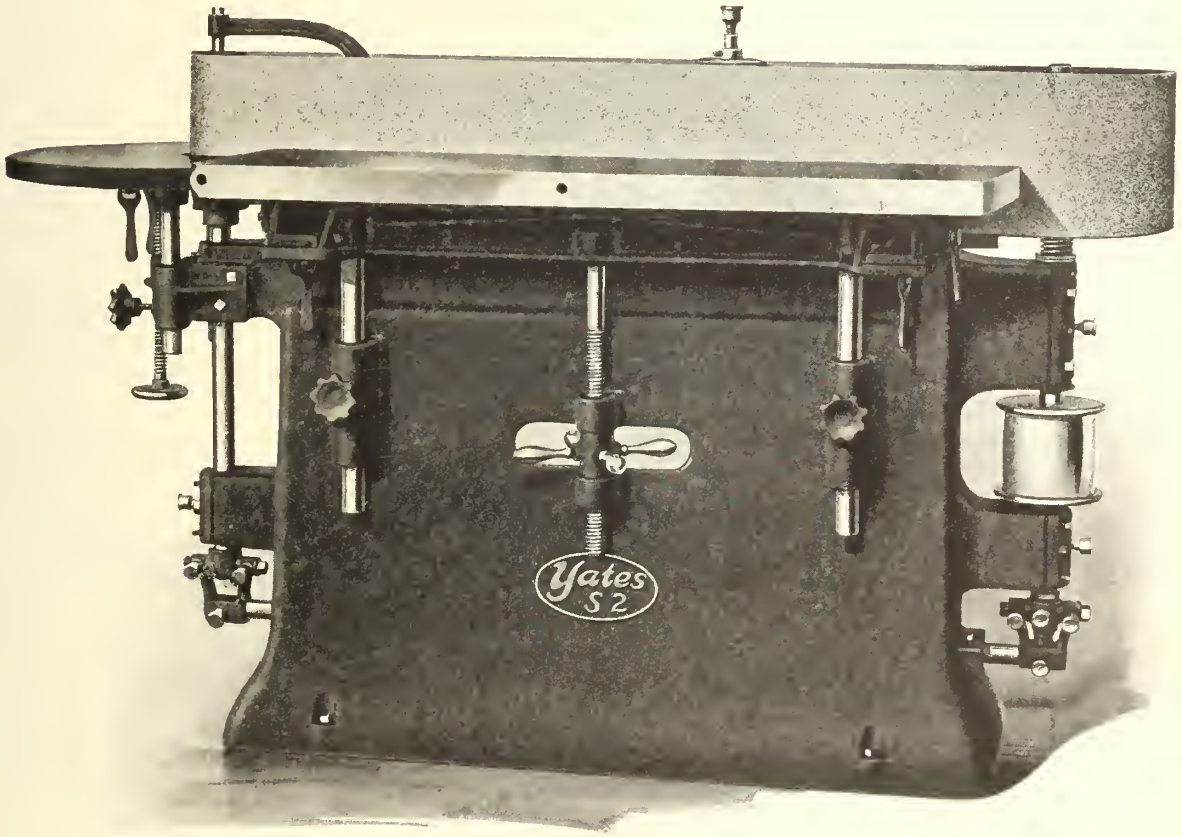
YATES

TYPE S-2

EDGE SANDER



The Type S2 is a very useful machine for furniture factories and woodworking shops, for sanding straight stuff as well as handling all the irregular shapes. Main tables can be tilted for sanding stock with bevelled edges.
Drums oscillate which gives stock a fine and even finish removing ridges and scratches which would otherwise appear if sand belt ran straight. A 10 inch sand belt is regularly furnished. Gladly send you circular with full particulars on this machine upon hearing from you.

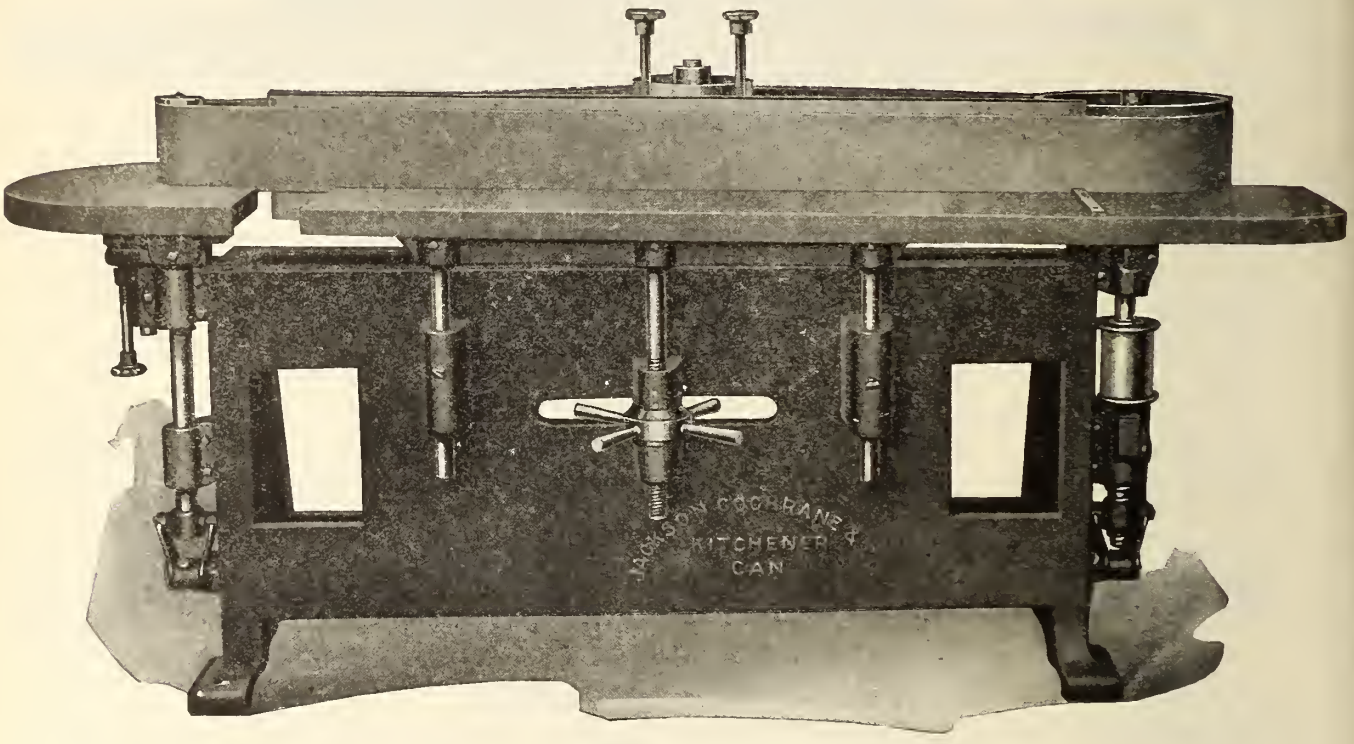
No. 272 OSCILLATING



No. 272
Oscillating Belt Sander for Edged and Shaped Work

This style of belt sander has a capacity several times greater than sanding drums or spindles. The high speed sand belt covers a long surface and retains its sharp and fast cutting properties. The long travel of the belt gives it an opportunity to cool off between contacts, whereas on drums and spindles, where the sanding surface is small, the wear is continuous and in one place.

It will also finish practically any piece of straight or bent work that can be supported on the tables or held against the platen or sanding rolls.

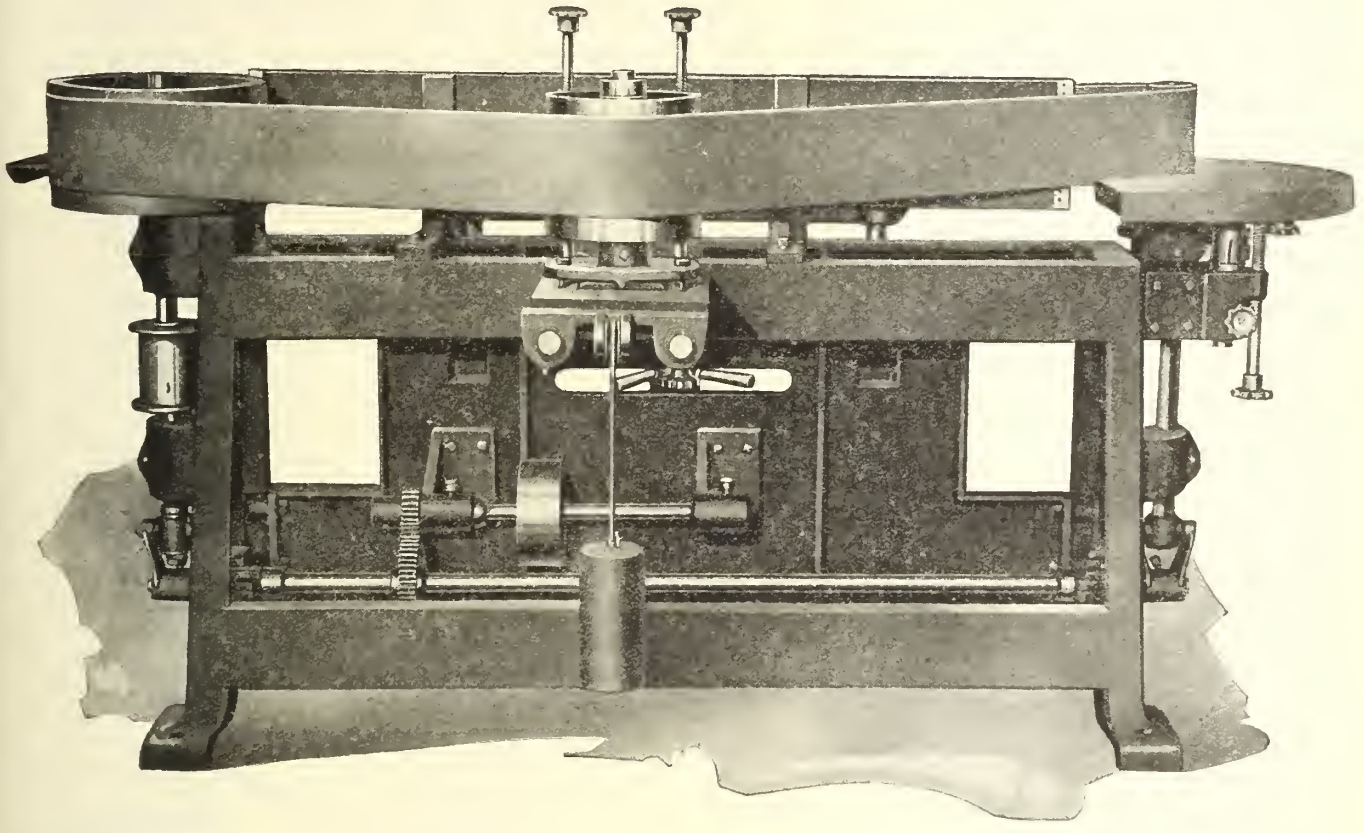
The design and construction eliminates all chance of vibration, thus insuring a perfect sanding contact. The tables provide an even and accurate support for the work, and as the belt travels with an oscillating movement, a perfect finish is assured.

The tables are the proper height and permit the operator to handle his work in a natural position. Numerous sizes of sanding rolls, special forms for shaped work and non-revolving sanding spindles may be used for sanding a large variety of work. The long platen between the sanding pulleys may be removed and replaced with special forms for any work having rounded edges.

This sander is so constructed that a number of stationary forms may be used for special work.

Jackson, Cochrane & Co

BELT SANDER



Features of our No. 272 Oscillating Belt Sander

Heavy construction eliminates vibration.

Long belt surface prolongs life of sand belt.

Oscillating movement prevents scratch marks.

Belt pulleys covered with heavy coating of rubber provides a good driving surface and a perfect sanding cushion.

Large tables and each adjusted independently of the other.

S.K.F. ball bearings in small belt pulley.

Improved belt tightening device.

Convenience of operation.

Large capacity.

Very moderate price.

Large descriptive circulars now ready. Send for one and get full particulars on this Sander.

SPECIFICATIONS

Large Sand Belt Pulley....14" dia. x 8½" face
Small Sand Belt Pulley...3½" dia. x 8½" face.

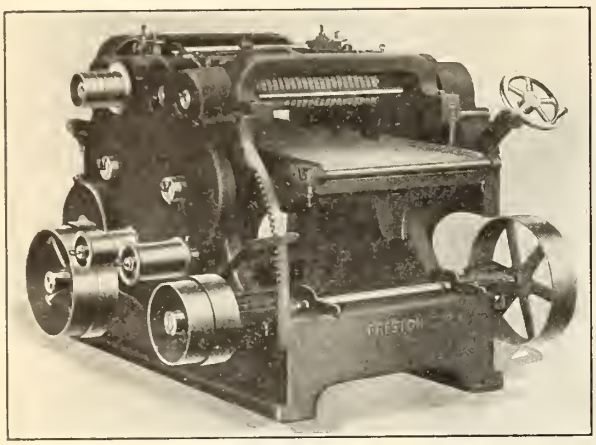
Manufacturers of Woodworking Machinery

Kitchener, Ont.

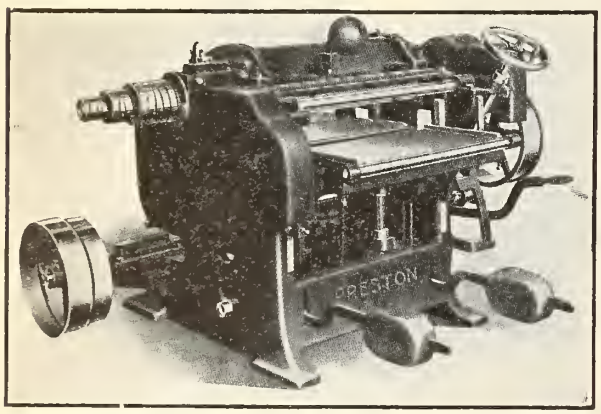
"Preston" Woodworking Machines Mea



No. 123 "Preston" High Speed Ball Bearing Surface Planer

This cut shows planer equipped with specially selected S.K.F. ball bearings, sectional roll, and sectional chipbreaker, round cylinder with four high speed knives, and arranged to receive Stockridge electric knife grinder and jointer. Cylinder speed, 5,000 R.P.M.

Two points are guaranteed: (1) It will reduce your sanding costs (2) It will increase your production.



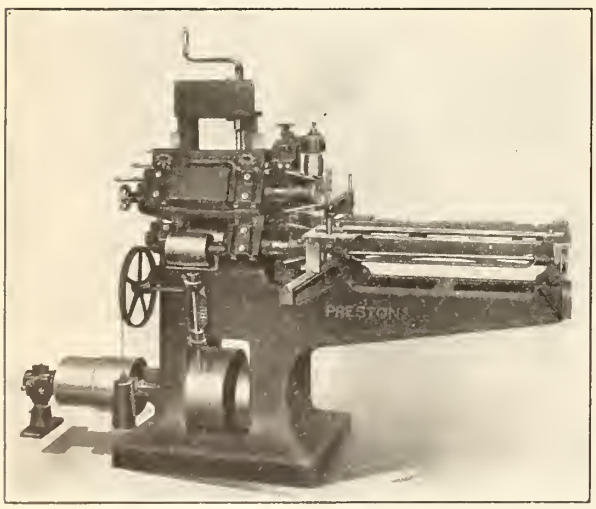
No. 121 "Preston" Heavy Pony Planer

This cut shows standard machine. Can be built with:

(1) Straight roll or divided rolls or sectional roll and chipbreaker.

(2) Square cylinder or round 4 knife cylinder.

(3) Babbit Bearings or S.K.F. Ball Bearings.



No. 184 "Preston" Tenoning Machine

Features of Construction.

(1) Genuine Whitney self-lubricating bearings.

(2) Powerful belt drive.

(3) Large heavy base and very rigid in all parts.

(4) Practically all adjustments made from front of machine.

The Preston Woodworking

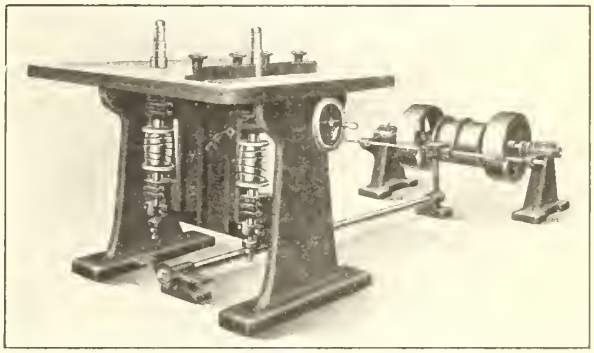
PRESTON,

We are Sole Manufacturers of and Agents in Canada for the Eaglesfield Patented Beltless Swing Saw

arger Output and Lower Expense

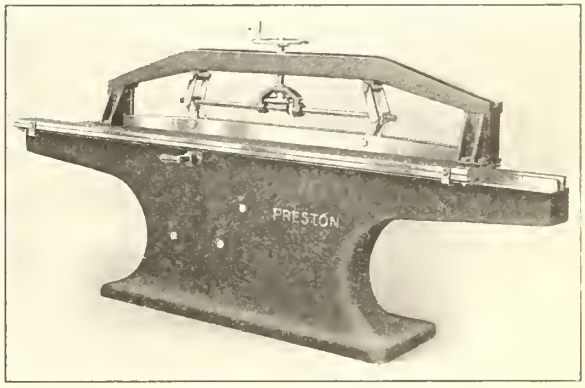
No. 164 "Preston" Ball Bearing Shaper

Designed to meet the requirements of concerns needing a lighter and less expensive Shaper than our No. 162.
Made with:
(1) Babbit bearings, plain countershaft.
(2) Ball bearings, plain counter-shaft.
(3) Ball bearings, special countershaft.



No. 181 "Preston" Veneer Jointer

The only veneer jointer that will effectively joint buckled veneer. Designed for the purpose of making commercially perfect face joints, butt or crosswise, as well as lengthwise of the grain on the highest figured Circassian Walnut or Crotch Mahogany Veneer. As rigidity is an essential feature of this type of machine, special care was taken in its construction. The frame, which is of cored section, is cast in one solid piece.



Eaglesfield Patented Ball Bearing Motor-driven Beltless Swing Saw

The special features of this saw are evident from the illustration. The motor is attached directly to the saw mandrel, which is supported in S.K.F. ball bearings. No belts or gears are used and the saw may be hung anywhere, regardless of the position of the shafting.

No. 132 "Preston" 36" Band Saw

Made with or without guards. The wheels are all steel, covered with solid rubber bands, ¼ in. thick. Solid web lower wheel is supplied when desired.
We guarantee that breaking of saws will be reduced to a minimum on this machine by reason of our almost perfect tension device and style of guide.
Supplied with 3 H.P. motor for individual drive if desired.

BOOKS FOR SALE

The following books are offered at special prices subject to previous sale:

"Machine Molder Practice," recently published by the Practical Books Co. 172 pages, 100 illustrations. Flexible leather binding. Price $3.00.

"The Utilisation of Wood-Waste," by Ernest Hubbard, Third English revised and enlarged edition, 236 pages, illustrated. Published in 1920 by Scott, Greenwood & Son. Price $2.00.

"Modern Practical Joinery,"—A comprehensive treatise on the practice of joiner's work by hand and machine. For the use of Workmen, Builders, Machinists and Architects. Containing a full description of drawing instruments and their use; tools, appliances and apparatus; methods and processes; joints and fastenings; woodworking machines; machine shop practice; preparation of work for machining; use of the steel square; house joinery, bank, office, church, museum, domestic and shop fittings, show cases, air-tight cases, splayed and shaped work; new materials and method, stairbuilding, foremen's work, fixing, and a description of nearly 150 woods suitable for joinery. Together with a comprehensive glossary and index. By George Ellis—fourth edition, extensively revised and much enlarged. With upwards of 1400 illustrations, including 20 double page and 41 photographic plates. Recently published by B. T. Batsford Limited, 570 pages. Price $12.50.

"The Kiln Drying of Lumber," a Practical and Theoretical Treatise, by Harry Donald Tiemann, M.E., M.F. Just published, by J B. Lippincott Co. 316 pages, illustrated. Price $5.00.

Seasoning of Wood; A Treatise of the Natural and Artificial Processes Employed in the Preparation of Lumber for Manufacture, with Detailed Explanations of its Uses, Characteristics and Properties, by Joseph Wagner. Published by D. Van Nostrand Co., in 1917. 274 pages, illustrated. Price $3.00.

"Modern Practical Carpentry"—For the use of Workmen, Builders, Architects and Engineers. Containing a full description of the methods of constructing and erecting roofs, floors partitions, scaffolding, shoring, centering stands and stages, coffer dams, foundations, bridges, gates, tunnels excavations, woods and half timber houses and various structural details. Together with new and simple methods of finding the bevels in roofs, setting out domes, steeples, etc. An account of failures in construction, and the theory of trussing frames. Also including a concise treatise upon timber; notes on the woods used in carpentry; various tables; a glossary of terms and phrases connected with carpentry; and a chapter on the uses of the steel square. With about 1100 illustrations. By George Ellis—second edition revised. Recently published by B. T Batsford Limited, 396 pages,—price $7.50.

IF you plan to remodel your kiln, our literature will help you —also your operator.

EVERY big new flooring plant built this year to dry hardwoods has chosen The Standard Dry Kiln except only one—consider what that means in the hardwood field.

What is a "Circulator?"
Do you know how it cuts down drying time—how it prevents checking? Ask for our free literature on this—it will pay you.

THE DRY KILN THAT DOES NOT Disappoint

The Only Heating System having ***both*** advantages—horizontal piping ***and*** also division into units.

Are you on our free mailing list? Get on—!

THE STANDARD DRY KILN

For literature on any points of drying or your problems, write us at 1542 McCarty St., Indianapolis—The Standard Dry Kiln Co.

1922 --- OCTOBER - NOVEMBER - DECEMBER -- 1923

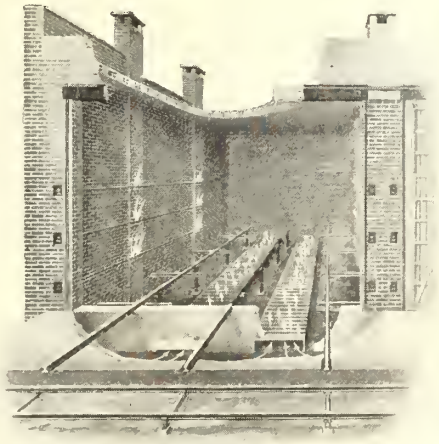
Three Months Until the New Year Arrives

Are you ready for a Bigger and a Better year's Production?

NATIONAL AUTOMATIC HUMIDITY CONTROLLED DRY KILNS installed NOW will assure you perfectly conditioned lumber. They are the fruit of over twenty years' experience in the designing, operating and manufacturing of lumber kilns by the best dry kiln engineers obtainable. Nationals owe their success to the constant research made by these engineers, and the executing of improvements to meet the new phases in the scientific application of their findings, as applied to the practical use of kilns. As a result NATIONALS have become the most perfect, practical drying apparatus on the market.

When installing a National you are not experimenting,—all experiments have been made at our expense. You are guaranteed absolute satisfaction in the production of cured lumber of the highest quality.

Business is daily growing in volume and all indications point to better conditions. Are your dry kilns adequate to handle a bigger and a better production during the coming year? If not, NOW is the time to bring them up to the desired standard. Whether it is a question of new kilns or the remodeling of the old, our engineering services are free. Kindly write us full details as to your problems and we will be pleased to respond. This will not obligate you in any way.



"The First Kiln in 6000 Years in which Humidity is Automatically Controlled"

COIGNET CHEMICAL PRODUCTS COMPANY
17 State Street NEW YORK CITY

"Casco" for better product

YOUR confidence in your product is shared by your customer when he knows that

WATERPROOF GLUE

grips the Veneers or the joints.

Write for "CASCO" Red Book—a manual on Veneers, Panel-making and Glue. Samples of "CASCO" on request.

"CASCO" is Incredibly Strong Mixed in Cold Water Most Economical

Casco-made woodwork can be subjected to extreme variations in temperature and moisture without fear of separation.

The Casein Manufacturing Company
Largest and Longest Established Manufacturers of Casein Products in America
15 PARK ROW, - NEW YORK CITY

U. S. Navy uses MONITE —*the practical waterproof* GLUE

WHEN the U. S. Navy uses a glue by its brand name it certainly must be waterproof.

Not only has Monite Glue withstood the severe test of use by the U. S. Navy, but it has withstood many exacting laboratory test as well. Five-ply birch panels held with Monite have been soaked in the laboratory for ten whole days. The panels were boiled for twelve hours daily and cooled off each night. At the end of the test the glue joints were still unimpaired.

The absolute water resistance and the wood preserving qualities of Monite Glue greatly enhance the value of any glued articles. The fact that it may be mixed cold and in a remarkably short time, the greater spread and the quicker set—all save time and labor in the glue room and cut down your glue line cost.

Just what this amount is in dollars and cents can only be shown by one of our experts in your factory. Write us and we will arrange for such a demonstration without obligation on your part.

The Six Economies of Monite Glue:

1. Takes half as long to mix.
2. Gives a greater spread.
3. Sets more quickly.
4. Average shear strength 2641 pounds per sq. in.
5. Uniform quality varies less than 1% guaranteed.
6. Improves the product, gives longer life.

Monite Sticks To Its Job.

Two Definitions—Which Is Most Practical

FOR YOU TO USE?

Compo or Composition Carvings:—A puddy like compound made up of whitening, glue and rosin, is **not** immune to atmospheric conditions. Is **not** fiberous in nature. Has little or no grain. Is **not** sharp in detail. Can **not** be guaranteed against chipping. It is **not** immune to cracks due to expansion and contraction. Does **not** stain like **wood**. Should **not** be found on good furniture.

Keep up the spirit of the times, properly decorated furniture will always be in vogue. Do not kill Period Furniture by decorating the same with unreliable carvings.

"Fibro" Wood Carvings:—A reliable wood product. The result of years of diligent effort. Inspired entirely because of the short-comings of puddy carvings. Having all the grain effects of wood, sharp in detail, and truly artistic, all the qualities for absorbing stain and taking on a wood like finish. Last but not least a Canadian product.

Make Canada prosperous by buying Canadian products

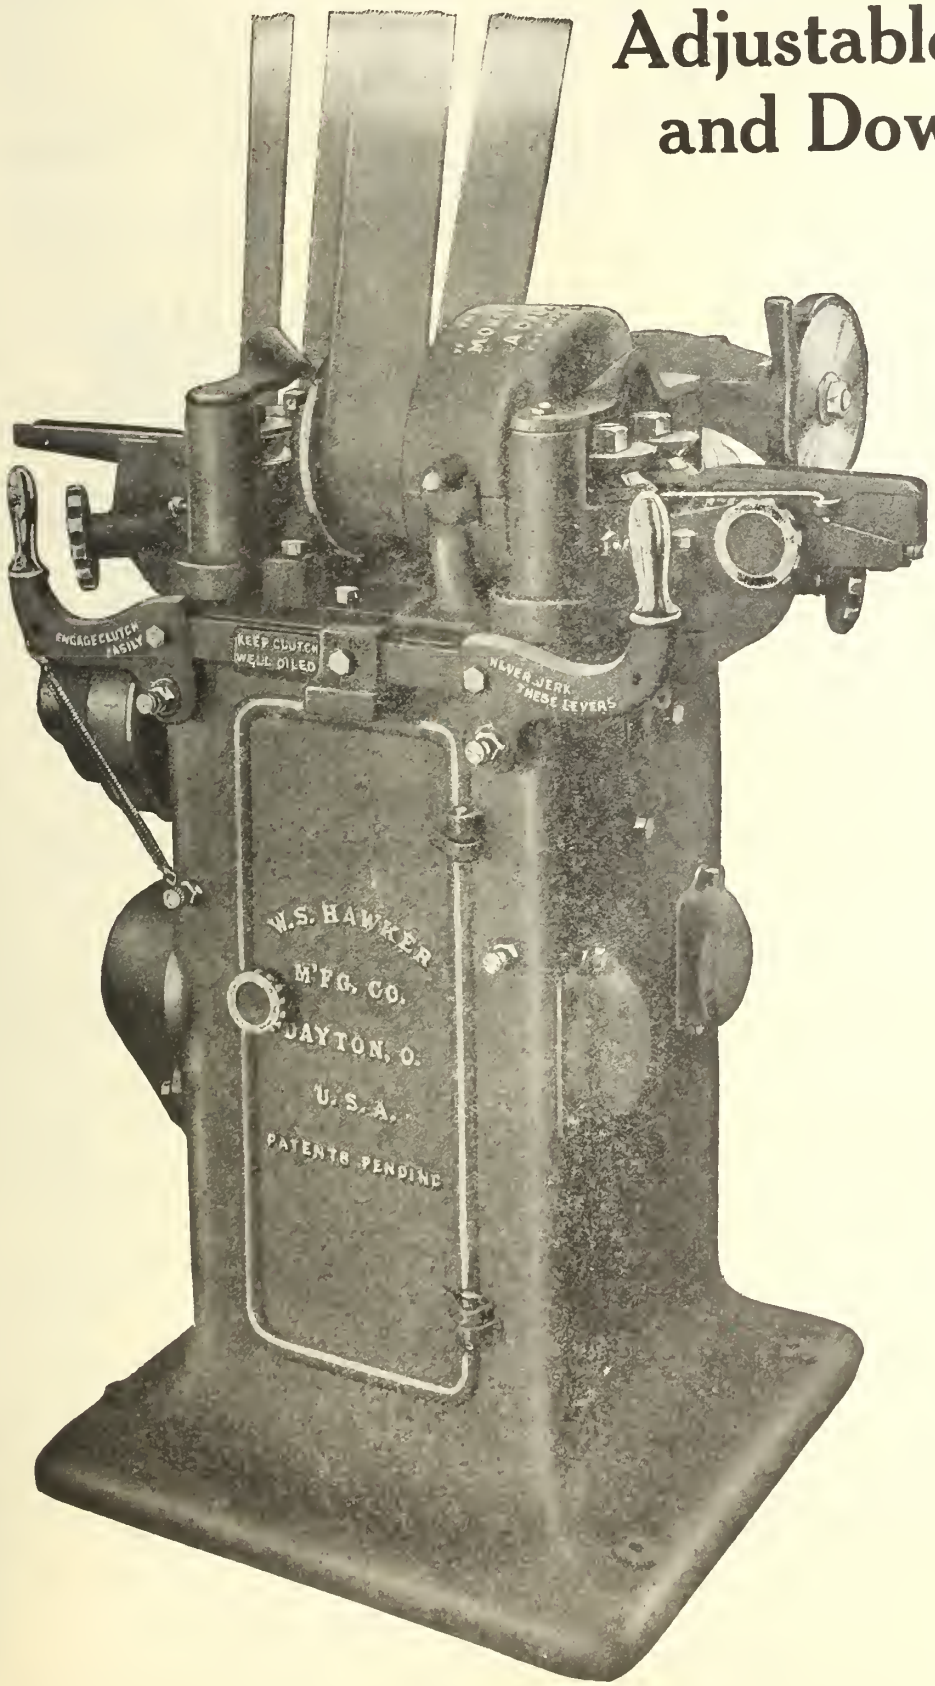
Coldbrook and Taylor, N. W. **Grand Rapids, Mich.**

The Money Maker— Adjustable Rod and Dowel Machine



Capacity 30,000 to 40,000 lineal ft. per ten hours on 7/8 or 15/16 mop or sweeper handle stock.
If you are using any dowel machine of less capacity, figure your daily losses in labor and business.
Write us what dowel sizes you turn, and whether hard or soft wood. Ask for our demonstration proposition to show you how to double your production of dowel stock at the same labor cost.

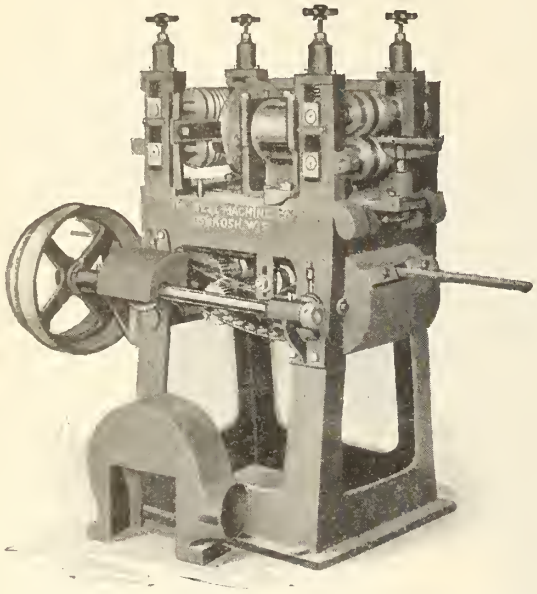
The machine that is sent under a guarantee to show you a gain of from 100 to 400 per cent before you buy it.
The improved dowel machine that 90 per cent of the largest and oldest machinery builders and dealers now endorse and recommend in preference to the solid chuck machines they themselves previously built.
One cutter head turns from ¼-in. to 2-in. diameter.
Turns hard or soft wood equally well.
Handles heavy, oversized squares.
No choking of the cutter head.
Smooth stock.
Accurate sizes.
Works stock as short as five inches.
Rolls automatically center variations in squares.
Machines built to turn from ⅛ to 6-in.
We want to hear from every user of a solid chuck dowel machine.
We can save you from one dollar out of every two, to four out of every five that the operation of solid chuck machines costs you.
Engagements for competitive test solicited.
Formal orders not solicited. All sales made after demonstration.

The only question is, are you willing to cut cost of your dowel turning to one-half or one-third of what it costs with any make of solid chuck machine?
Machine delivers the goods before you buy.
State conditions of stock closely
Special conditions require special equipment.

W. S. Hawker Mfg. Company, Dayton, Ohio

Make Your Own Dowels With the "BELL" Machines

The Fastest and Most Practical Equipment For the Purpose



Adjustable Rod and Dowel Machine

The fastest dowel machine in the world.

Constructed to withstand the heavy and constant strain to which this type of machine is subjected.

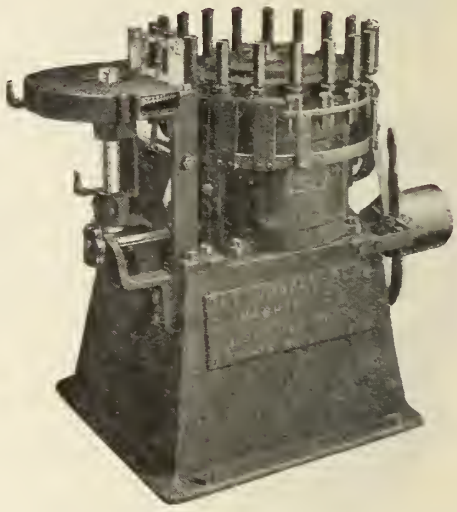
Equipped with a universal four-knife cutter head adjustable to turn rods of all diameters from ¼" to 2" in either plain, spiral groove, longitudinal groove, or imitation reed wind. Special machine for turning rods of larger size.

Cutter-head mandrel is mounted at each end in ball-bearings of the highest grade.

Out-going feed rolls have combination of grooves so that many sizes can be made without changing feed rolls. The in-going feed rolls are adjustable for all sizes of squares.

Will work stock as short as 4½ inches.

Furnished with countershaft or motor drive.



Dowel Cutting Off and Pointing Machine

This machine is for cutting off and pointing dowel pins from long rods.

It will cut and point dowel pins of all diameters up to ¾", and in any length up to 6 inches.

Capacity of this machine is from 300 to 400 pins a minute. Any boy can operate it.

All working parts are completely enclosed and thus protected from dust and dirt.

Absolutely no danger to operator.

The floor space required by this machine is only 22" x 36".

Tight and loose pulleys on machine.

Furnished with belt or motor drive.

Pyramids of Sand vs. OPENKOTE

Garnet Finishing Paper

THE surfaces of ordinary finishing papers are in reality uneven series of isolated *pyramids* or peaks of "sand"—kernels indiscriminately piled on top of one another. The high peaks are the cause of scratching in finishing work. Contrary to the usual impression they do not improve the cutting power of the paper, but shorten its life.

Magnified section of ordinary finishing paper

THE lower layer of kernels (*the real cutting surface*) in the above type of papers cannot start to work until the isolated pyramids of super-imposed kernels are worn down. During this process the danger of scratching is always imminent.

Magnified section of Behr's OPENKOTE Garnet Finishing

In OPENKOTE Garnet Finishing no kernels are interfered with, blocked, or covered by others. *Every grain is on the same perfect level,* cutting uniformly, with the same pressure, *and all at the same time.*

The abrasive surface of OPENKOTE Garnet Finishing is smooth and even, yet open, and constantly presents maximum roughness to the work. This is why OPENKOTE lasts longer and cuts faster and cleaner than ordinary finishing papers. It will not slide or scratch.

Behr's OPENKOTE Garnet Finishing is scientifically coated by a process exclusively our own. Its many technical superiorities, not visible to the naked eye, enable the artisans who use Behr Products to attain the finest finishes possible—smooth, even, and scratchless.

Send for samples of Behr's OPENKOTE Garnet Finishing for comparative tests on your own work. A post card specifying grades desired will bring them, without charge.

Walnut?—Yes,—Good Walnut?—Yes!
Pickrel

Walnut's sheer beauty, strength, uniformity and permanence brought it in a few years to unquestioned supremacy in furniture construction. Dominance in furniture proves but the beginning. This surpassing merit is every day compelling increased use in new cabinet fields. Pickrel walnut veneers fill an important place in this wider development. A limitless selection of quality veneer logs, careful and skilled manufacture and a constant stock of five million to seven million feet of nicely assorted woods have given Pickrel walnut veneers a special significance. Buyers will appreciate the responsible, conscientious and experienced representation through which Pickrel veneers are offered at their respective plants. It assures the closest possible conformity to the individual requirements of each—meaning less cost in working and a better product.

The way it goes to our Customers

Air Dried or Kiln Dried?

Kiln dried stock will mean an advantage to you—a material reduction in weight with a resulting reduction in freight cost. Kiln-drying in our plants means the latest and most improved methods together with efficient handling.

Any of the following items in Southern Hardwoods can be shipped promptly from our band mill at Little Rock, Arkansas. Band sawn in our own mill, dry, good widths and excellent lengths, this stock graded according to National Hardwood Lumber Association rules represents a good value for you.

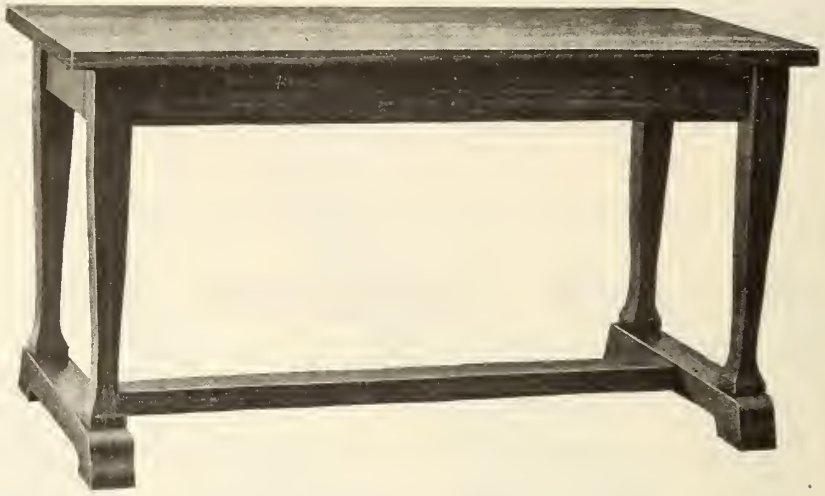
THE BIGELOW-COOPER CO.
BAY CITY - - MICHIGAN



This handsome piano bench is made of

Canadian E C & S *Birch*

THERE is a firm in South Acton, Mass., U.S.A. who specializes in the manufacture of Piano Stools and Benches.

It is significant that this firm with a wide reputation for the quality of its products should be large users of Canadian Birch as supplied by Edward Clark & Sons Limited. It speaks well for this versatile Canadian wood with its close even texture and beautiful grain—adaptable to the most artistic and yet practical uses.

Another big factor contributing to its popularity is its economy. For while Birch closely resembles Mahogany and has indeed many of the good qualities of that wood, it is much less expensive.

Try a carload. We know you will be more than pleased with your purchase.

Delivery and Costs

The Ontario millman's query in the last issue, "What effect has prompt delivery on costs?" finds an echo in a letter just received from a Pacific Coast woodworker who complains that customers have a tendency to wait until the last possible moment when placing orders and then expect and insist on immediate delivery. His experience has been that orders for rush delivery cost considerably more than if allowed to go through in the regular course. In this he is on common ground with every other millman who has had any experience with the dilatory buyer—and what millman has not had dealings of this kind? Indeed, the customer who shops around for a month or so and then expects immediate delivery, is one of the banes of the woodworking industry—one of our sash and door friends the other day even went so far as to call him a parasite, who curbs the industry's ability to give proper service and do adequate justice to prior orders and interferes with plant efficiency and manufacturing costs.

There is no doubt that the prevalence of the practice referred to has a very pronounced effect on costs. The experience of our British Columbia correspondent, as related above, testifies to this, and many others with whom we have discussed the subject agree that costs are higher when a quick-delivery order goes through the plant—higher not alone on the rush article but also on the routine lines, the production of which has been necessarily delayed while the plant organization is adjusted to care for the special job.

This matter takes on serious proportions when a millman writes thus:—

"While we recognize that there are often legitimate reasons that prompt a customer to demand exceptionally quick delivery, we also are aware that such requests most generally come from those who are either over-dilatory in their buying or have been testing out the market for a considerable period in order to save the last nickel. This class of purchaser we are anxious to eliminate and to this end we have established a rule that the only claim to priority is early receipt of the order. With this our working principle, we have been able to build up a satisfied clientele through the consistent service we are able to give, coupled with satisfactory prices which are based on a cost of production that is not augmented by the necessity of handling quick delivery orders that are quick delivery only because the customers were so lackadaisical as not to realize their needs soon enough."

Many other millmen will readily join in commending this attitude although some manufacturers may possibly not like to be quite so severe in condemning the dilatory buyer or quite so hasty in attempting to eliminate him. However, the point is that delivery plays an important part in the matter of costs—a part that has, perhaps, not been sufficiently realized. In view of the vital importance of delivery, therefore, will not our readers cite their experiences that some idea of the influence of this factor may be obtained? A frank discussion that will do much to throw light on the subject is, therefore, encouraged and welcomed.

The Lumber Consumer's Interest in Grade Standardization

Any movement that aims to secure a more perfect formulation or definition of lumber grades and nomenclature and more adequate guarantees for the consumer of lumber is one that commands our hearty endorsation. More especially do we, as lumber consumers, need to be taken into conference on the matter of grade standardization, for the wood-using industry has certain definite requirements which, we fear, have not often been taken into consideration when mapping out a grading schedule. Many thinking people feel that there is a definite need for some revision in grading practices, the thought in this direction being well expressed in a letter which has recently been received by the "Canadian Woodworker." The writer of this states:—

"There has been in some quarters a large amount of loose thinking on the question of the proper function of grading and inspection rules and some have seemed to take the superficial view that their chief use is for settling disputes. Others say that what the grading and inspection rules are make little difference because whatever they are, prices will be adjusted to make them reasonably conform thereto. A very little reflection will disclose the fallacy of such reasoning because the primary object of grading rules should be to enable those who use the lumber—the fabricating manufacturers and consumers—to specify what they want and be able to get it, but the specification of what the consumer wants and needs, must have relation to what the producers are able to produce and supply. Therefore, the requirements of the consuming industries and the possibilities of the production industry must be considered not as matters of theory, but as facts. In other words, a proper formulation of grades must proceed upon an adequate survey, ascertainment, collection, compilation, and analysis of facts respecting both phases of the industry. When this is done, then grade rules can, as a result and by the united effort of the producers and consumers, be formulated so as to enable the fullest and most economical manufacture of the logs into lumber and the most adequate service of consumption

at the least cost and with the minimum of waste, and, therefore, with a very considerable conservation of timber resources."

As we all know, there has been growing up in the United States on the part of certain hardwood lumber manufacturers a distrust of the old rules relating to lumber grading and nomenclature, with the result that there was formed the Hardwood Manufacturers' Institute, whose avowed purpose is to develop rules embodying a standardized nomenclature "scientifically conceived and formulated, based upon practical facts of experience and of utility. These should be formulated by the manufacturers working in the fullest and closest co-operation with the consumers." We do not need to concern ourselves at this moment with the controversy that has grown up in lumber-grading circles on the other side of the line, nor do we need to pass judgment on either the Hardwood Manufacturers' Institute or the National Hardwood Lumber Association. The one point that interests us at this time is that any movement toward the improvement of grading practice should by all means take into account the consumers of wood so that the specifications that determine grade classification shall not be purely arbitrary but have some relation to the requirements of utility. Hardwood producers and hardwood consumers can certainly co-operate to such an extent as to determine a grading classification that will mean putting forest products to a better and less wasteful use. Canadian hardwood users will, certainly, realize the extent to which they are concerned in this vital matter, and we are sure that Canadian hardwood manufacturers will be willing to co-operate to the mutual advantage of the whole industry.

Advantages of Ready-Cut Dimension Stock

Industrial investigations made by the United States Forest Service on the production of small dimension stock at factories of the chair industry substantiate the chief claims made for ready-cut dimension stock. These studies revealed interesting waste and cost data which show conclusively that the advantage of obtaining small-sized stock from the mill are not all on one side. As the following summary shows, the factory owner and the lumberman would be equally benefited.

For the factory owner or wood user, ordering ready-cut dimension stock from the mill would:

1. Permit the purchase of clear, high-grade, ready-cut stock at prices equal to or less than those of clear high-grade lumber.
2. Eliminate the freight on waste which often runs from 15 to 55 per cent of the cost of the material f.o.b. factory.
3. Reduce the amount of the stock stored in the yard, and thereby reduce the amount of working capital required.
4. Reduce the real estate investment by decreasing yard and kiln space.
5. Largely eliminate the cutting-up room and thereby conserve floor space and labor or make it available for increased production.
6. Lower overhead costs by decreasing insurance, depreciation, real estate investment, working capital, power, and non-productive labor.
7. Solve the problem of hauling and carting waste.
8. In general, lower the cost of the finished product.

For the mill owner or lumberman the production of small sized stock would:

1. Offer opportunities for the utilization of short and crooked logs now left in the woods.
2. Lower the present stumpage by increasing the yield over the estimate.
3. Reduce the logging costs by increasing the amount of material obtained per acre.
4. Reduce the fire hazard by lessening the debris left in the woods.
5. Increase utilization at the mill of low-grade material and present-day waste, such as slabs, edgings and trimmings.
6. Decrease the investment per unit production.
7. Concentrate at the mill the waste now divided among woods, mill, and wood-using factory, and thereby afford greater opportunities of utilizing it.
8. Create a stabilizing influence on the entire industry.

Besides offering these immediate advantages to the industry, the production of ready-cut dimension stock at the mill would constitute a big step toward the conservation of the rapidly disappearing hardwoods. It would provide for a future supply, stabilize woods, mill, and factory labor, and prolong the life of the wood-using industries.

The Annual Financial Review

The Annual Financial Review (Canadian) for the year ended June 1922 has just been issued by Messrs. Houston's Standard Publications, Stock Exchange Building, 84 Bay Street, Toronto. To the man or woman who has money to invest, whether in large or small amounts, this is a publication that may well pay for itself many times over during the year, for it is a carefully revised precis of facts regarding Canadian securities. The information contained includes the latest annual statements of banks, railways, public utilities, industries of every sort, loan and mortgage companies, mines, etc. List of bond and brokerage houses are also given, with the standard charges for buying and selling. In addition to the annual report of each company, there is also printed in nearly every case the record of the buying and selling transactions in the different stocks for a number of years, thus giving the investor an opportunity to judge, at a glance, whether the past history of a stock is such as to make it a suitable investment for his particular needs.

Contrary to the opinion held by most inexperienced investors, comparatively few fortunes are the result of speculation. Insurance companies tell us that 95% of our population are more or less dependent upon their relatives in their old age;this in spite of the fact that perhaps 50% of our people have developed in a greator or less degree the saving habit and have placed their money at one time or another in what they believed to be "investments." The secret of old age dependence must, therefore, be due to the lack of knowledge about investments. For these reasons, it would appear that no person with money to invest could do better than pay $10.00 for a copy of this Annual Review and make a careful study of its contents. If an investor has large quantities of money at his disposal this expense represents an infinitesimally small portion of the savings that may be effected through accurate knowledge. For the small investor, whose all is counted in thousands, it goes without saying that a high factor of safety is of prime importance.

How to Bring Down Your Factory Costs

The Installation of New and Improved Equipment Alone is no Assurance of Lower Manufacturing Costs—Establish Basic Standards of Operation as a Goal Toward Which to Work—Create Employee Interest

By L. R. Wright*

In glancing through a morning paper, recently I noticed an advertisement bearing the same heading as this article. The two main points mentioned fit in so well with my own thoughts that it migh be of interest to repeat them:

"The first step: From the experience of successful manufacturers, pick the methods which improve upon the methods at present used in your plant.

"The second step: Compare the output from your present equipment with the output of the most modern equipment now available for your use."

The first step suggests that it is advisable to learn how other progressive manufacturers are cutting their costs, while the second suggestion points to the value of standards as a basis for comparing the relative productiveness of your plant, of your men, and of your equipment.

Most woodworkers are willing to admit that bringing costs down to where they should be is one of the most important problems confronting the factory executive. This is entirely different from recording costs, as there is little or no relation between costs as they are and costs as they should be. In each plant, however, there is a definite minimum cost for each individual operation. This will vary in different factories, depending on the equipment, layout, class of work and the productiveness of the workmen.

Before costs can be reduced to what they should be with any degree of certainty, definite minimum standards are necessary not only to indicate how much higher present costs are than need be but to establish a definite goal toward which to work. With such standards available the question resolves itself into the problem of bringing individual operation costs to as near the minimum standards as conditions permit.

Highly Specialized Work

The reduction of costs is in reality highly specialized work. When there is a cost system to be installed the first thought is to turn to a cost accounting organization. This is because such an organization is in a position to give value, specialized service, based on a broad experience in that particular field. Similarly, if confronted with problems in management or executive control, resort is made to the management engineering organization, for they in turn are able to give special service in that particular field. Carrying this thought further, an organization specializing in cost reduction work should be in the best position to secure worthwhile results in that particular direction.

Someone may suggest that if they want to cut the cost of some particular operation all that is necessary is to install some new or special equipment. Such a procedure might lower the cost on that particular item, but it would not necessarily bring it down to as low as it should be. To carry such an idea to its logical conclusion many woodworkers would be faced with the necessity of replacing every machine in their plant. This would entail a heavy outlay and while undoubtedly they would enjoy lower manufacturing costs after such a change they would have no assurance that the new figures would represent minimum cost based on the improved conditions in the plant.

The most noteworthy showing in the direction of lower costs can be made by having the productiveness of your present equipment and of your employees brought up to what it should be, based on basic standards, which show definite minimum operating times and direct labor costs. When that has been accomplished, you have established minimum costs as far as your present equipment and plant conditions are concerned.

The Human Element in Cost Reduction

The human factor is an uncertain element in a problem of this kind, and must be given every consideration if worthwhile results are to be obtained. Unless the equipment is operated to as near capacity as possible, and unless all waste effort has been eliminated, production costs are not as low as they might be. This suggests one reason why new equipment does not always effect the economies that were expected. The output of a new machine might be considerably greater than the equipment it replaced, but unless the stock is put into it in proportion to such increased capacity the output of the new machine is little if any better than the old one.

The recent experience of a furniture manufacturer might serve to illustrate this point. The capacity of an old planer was so low that it retarded production in other sections of the machine department. To overcome this condition a modern high speed machine was placed in operation. Shortly after this it was noticed that conditions in the machine department where the same as before the change. An investigation brought out the fact that the planer operator was carrying the same feed on the new machine that he had been accustomed to on the old planer, this in spite of the fact that the new machine was equipped with a round cylinder carrying four knives and would do good work at fast rates of feed. Here was a case of where increasing the capacity of the equipment did not increase the capacity of the operator.

Payment for Labor

The elimination of lost motion, the reduction of waste material and of unproductive labor and the simplification of operation all have their place in a cost reduction program. But before the costs are brought down to the minimum the hearty co-operation of all employees must be secured and in addition they should be given an incentive to do their best. Many employers have endeavored to create an incentive through paying on a piece rate basis but this method has been so abused that is has lost

*Statistician, Forest Products Engineering Co., Chicago.

favor. In addition the piece work rates were not usually based on a definite knowledge of what the work is worth but were guessed at or fixed so that the employee could earn about a fixed amount a day. Another drawback with piece work is that the rates must be raised and lowered with every change in general wage levels and furthermore, it is not practical to rate new articles and new designs until after a lot or two has been put through.

A bonus system is sometimes employed to overcome some of the objections to piece rates but here again the bonus is often in the form of an arbitrary amount added to the regular wage. In some cases, it is given only when the production exceeds a certain fixed figure. In any event it usually ends by becoming a part of the regular weekly wage and is in reality an increase in pay under another name.

Using basic time standards it is a simple matter to fix rates, in time per hundred pieces, that are fair to both employer and employee. Being basic and being expressed in time such rates are not subject to change with every fluctuation in general conditions; thus they are usually permanent, yet through them the employees may be paid only for what they actually produce, and the more they turn out the more they earn. Wherever applied this plan is unusually successful for the employees recognize its fairness and its reliability and as they are paid for what they earn, not according to the time put in, the result is increased productiveness and lower costs.

Why Not Make Use of Bench Machinery?

Portable Equipment Will Save the Woodworker Time, Labor and Money—Being Adopted for a Wide Variety of Operations by the Furniture and Wood Using Industries

In the July issue of the "Canadian Woodworker and Furniture Manufacturer," we told of the origin of the portable bench machine idea—an idea which has spread into thousands of plants, large and small, and into more industries than the originator of the idea thought possible.

The modern pattern shop can hardly be without these portable 4" and 6" jointers, universal, plain and band saws. The disadvantage without such time savers is very apparent and no thinking management would permit that vast volume of fitting, trimming, cutting, etc., to be done by hand when it can be done by machinery, built to handle even the smallest pieces, right at the bench in a superior manner and in a fraction of the time.

The necessity for this type of machinery for the pattern shop was well known to the designer when he brought out his line, but as pointed out in our July issue, numerous other industries soon adopted the idea themselves, and for the most part unsolicited. It is the old story repeated of the mouse trap and the beated path.

In the Furniture Factory

In the furniture factory you will find these now famous portable bench machines on numerous operations. The operations on which some put the machines are not done in all plants, of course; therefore, the matter of adopting these machines has become a more or less of an individual proposition. A majority of the cabinet rooms in the principle centers are equipped with these machines because cabinet makers and assemblers have considerable fitting to do—why do it by hand when these machines built especially to handle even the smallest or thinnest stock with safety can be so conveniently located?

In many of the plants which operate on the piece work plan in the department the workmen have purchased these portable machines so that they can increase their income.

Some manufacturers of period furniture find that they can save time in gluing on blocks by jointing the block on a small bench jointer. They run the block over this small jointer, touch it with glue and stick it on—the joint is so nearly perfect the blocks stick without clamping.

The Bench Machine in the Pattern Room

The efficient handling of the designing room or pattern room has been a problem. This quite a few furniture, auto body and various other manufacturers have solved by installing these portable bench saws and jointers. The pattern men have to do a great deal of their work by hand—an expensive proposition—or they have had to journey out into the shop and use the machines out there—this also was an expensive proposition for they hamper production and change set up on machines; and above all, the new styles or ideas get noised about the shop and are soon more or less generally known to competitors. You will find these high priced pattern men now confined to one room which is equipped with these machines on which they can do all ranges of work down to the smallest; they are speeded up in this work and are far more contented with conditions.

The cabinet and pattern makers do not share the benefits of this idea alone for the carpenter finds great time saving possibilities in these portable machines and you will find that many of the more progressive contractors and builders and even repair men take these machines with them to the job. On new houses they get the light wires installed as soon as possible so as to enable them to operate their machinery.

House carpenters in hotels, department stores and office buildings also take these portable machines with them about the building on construction and repair work.

Why Not Cut Your Own Costs?

We could go down the seemingly endless list of uses for this type of machinery but space does not permit. We have touched on these few in an effort to make suggestions that may start thought along the line and cause many of our Canadian manufacturers of anything in which wood is used to study their operations and see if they too cannot cut costs on various operations by adopting the idea. We understand Canadian dealers are authorized to place these machines on trial so that any reputable manufacturer can try the machines for any operation on which he thinks he can make a saving.

Layout of a Woodworking Plant from a Safety and Efficiency Standpoint

One Handling of Lumber in Storage Yard, Kilns, Dry Storage and Cut-off-Saws—More Substantial and Better Arranged Buildigns—Machines Properly Selected and Located—Safety Features in the Power Transmission—Exhaust System and Other Adjuncts

By Burritt A. Parks*

So much has been written of late concerning safety and efficiency in manufacturing institutions that it would be presumptuous on my part to assume to advance any new principles or ideas along these lines. It may be of some value, however, to place emphasis on the interrelation between safety and efficiency in laying out a woodworking plant.

The woodworking industry, as is well known, is one of the oldest in existence, and yet in many ways it has been slow in development and loath to adopt new principles of manufacturing. The principal causes of this condition are that many of the men in the industry are of the pioneer type who have grown up in the trade and are to a certain extent satisfied with conditions as they exist and also because technically trained men in the executive positions are few and far between. The development of practically all modern industries to their present states of efficiency has been largely due to the technically trained engineer and it is only in recent years that the engineer's influence has been felt in the industry.

Accidents Have Demoralizing Effect

The majority of woodworking plant executives do not fully appreciate the intimate relation existing between safety and efficiency in the designing of their plants or the production of their product. It may be stated as a maximum that what is done to promote safety for the employee or plant will also increase efficiency. Accidents cannot help but have a demoralizing effect upon the employees, depending in amount upon the seriousness of the accidents, their frequency, and the extent to which the employees learn of accidents throughout the plant.

The attitude of the management is always reflected throughout the organization and a management which is indifferent to the adoption of safety measures and the promotion of accident prevention may expect a smaller production per man, a greater spoilage of materials, a greater labor turnover, increased overhead, and a general lack of esprit de corps on the part of all employees, on which a maximum of production and efficiency in manufacturing so much depends.

Safety promotion, as I take it, not only considers the prevention of accidents to employees, but also takes cognizance of the prevention of accident or loss to plant and equipment. We may therefore apply the principles of safety and efficiency from the lumber yard right through to the shipping room.

Much thought may well be expended on the layout of a lumber yard, although in many cases I am inclined to believe it receives the least attention of any part of the plant. A proper arrangement of sidings, storage yards, dry kilns, routing of lumber into the plant, fire protection, etc., will pay excellent dividends on the study and expense involved in obtaining the best solution of the problem that the site will permit. In the first place, economy in purchasing will dictate the size of the lumber storage facilities, which should probably hold a year's supply. This will allow of taking advantage of market conditions and avoid delays incident to transportation difficulties. To my mind the ideal storage yard should be equipped throughout with industrial trackage laid parallel with the receiving siding. With this arrangement lumber is unloaded and sorted directly onto small lumber trucks on "bunks" and then by means of properly located transfer tracks the truck loads are placed in the storage ready to be taken to the dry kilns.

Placing the Dry Kilns

The dry kilns should be placed in a battery as to be readily served by the same system of transfer trucks that serve the storage yard. A dry storage shed of ample capacity, also equipped with trackage, will allow for an accumulation of dry material and thus avoid delays in receiving lumber at the cut-off saws.

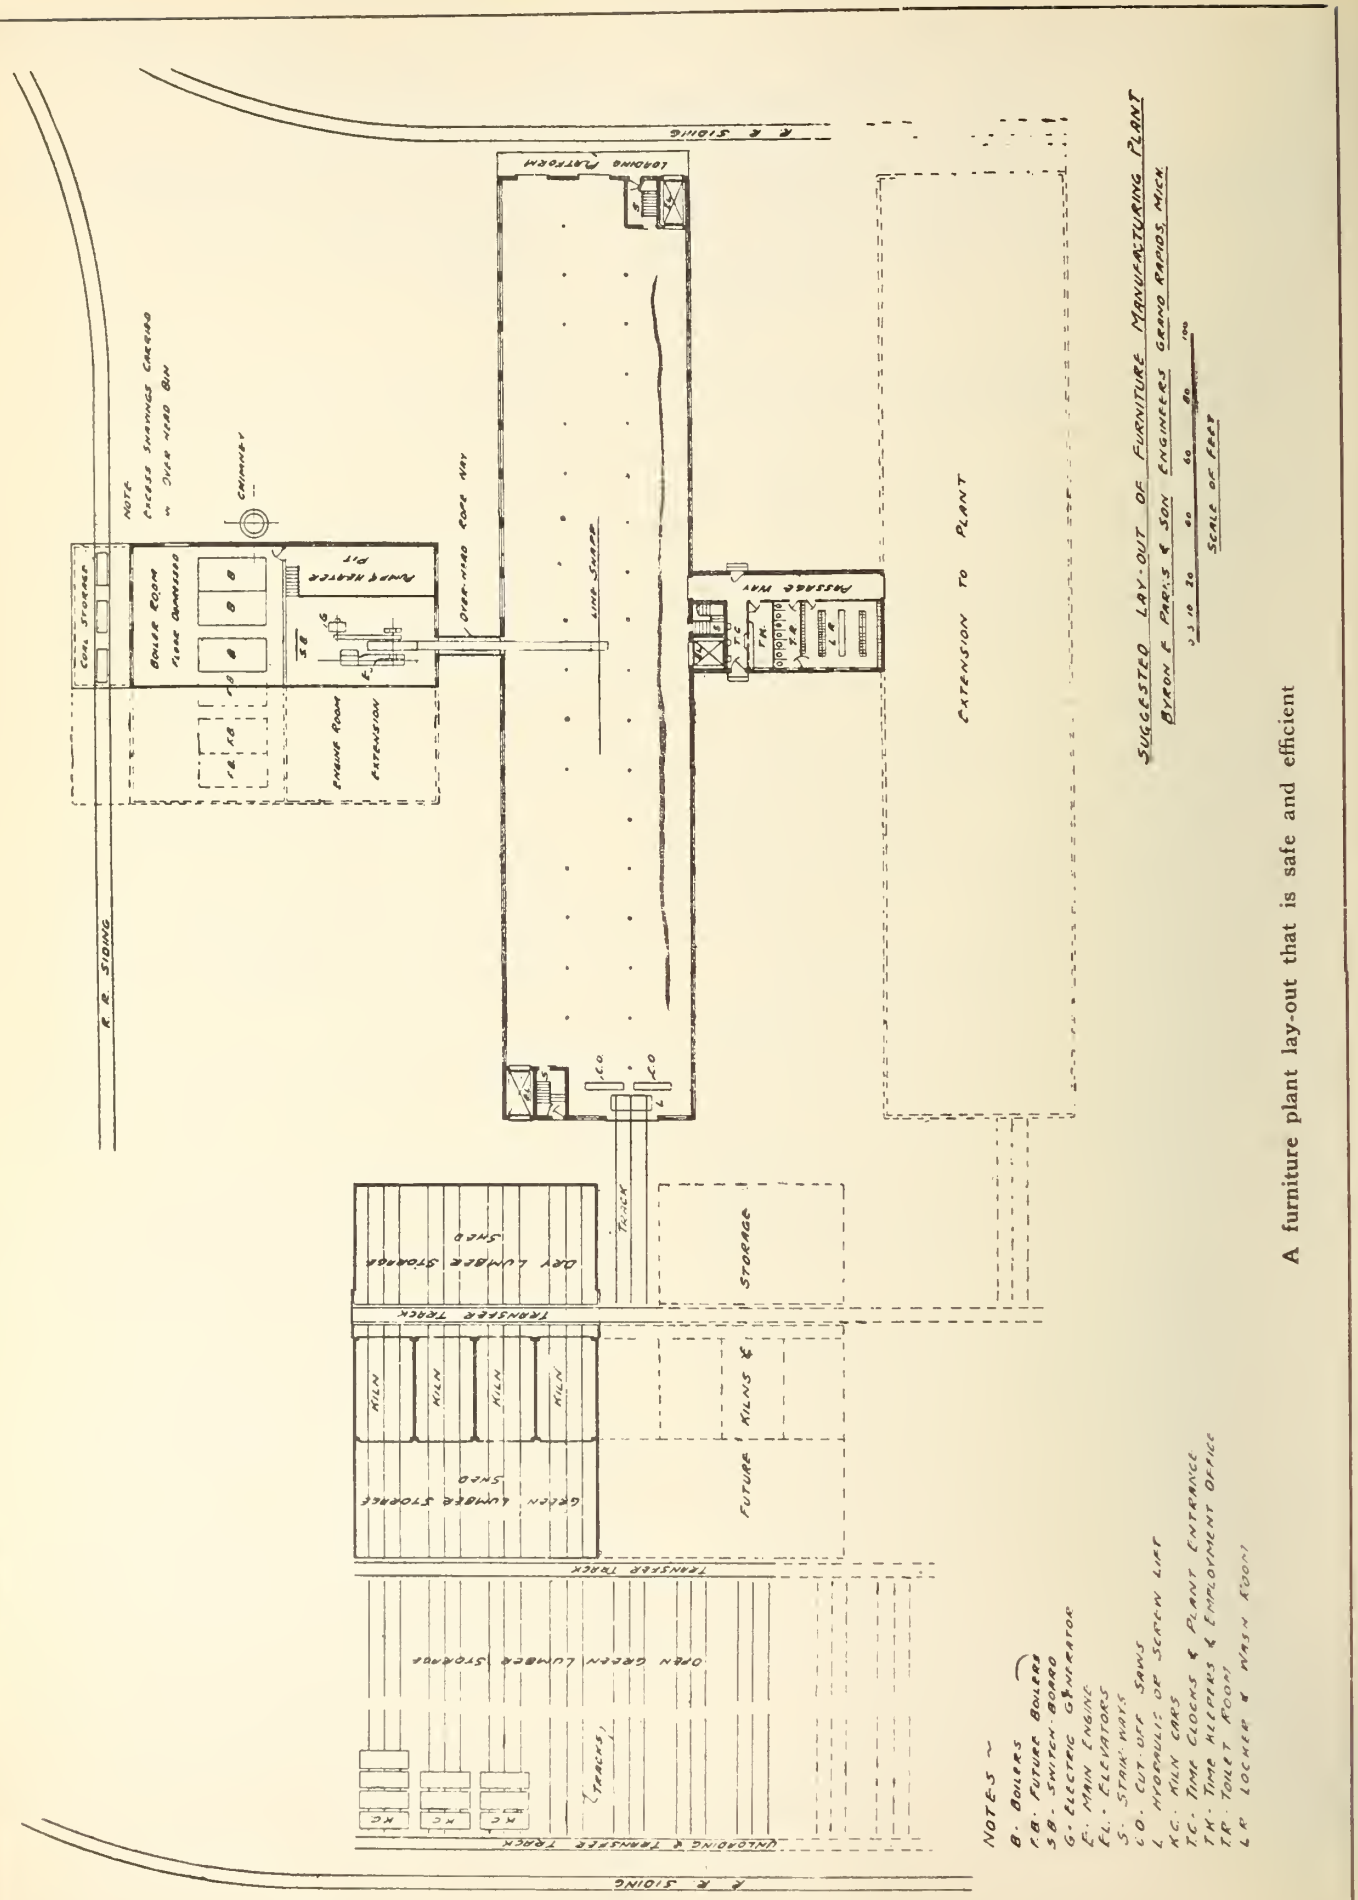
The same system of transfer tracks that serves the storage yard, kilns, and dry storage may be advantageously extended to the cut-off saws, where there should be provided hydraulic or screw operated lumber lifts.

It will be apparent that the arrangement of storage yard, kilns, dry storage, and cut-off saws outlined above will necessitate but one handling of the lumber from the railroad car until placed on the table of the cut-off saw. The efficiency in handling lumber and the decrease in opportunities for accident in this part of the plant is self-evident. This arrangement has the further decided advantage in that in case of fire in the storage yard the truck loads of lumber may be quickly moved, partially isolating the fire and allowing for access to same by whatever fire fighting methods are available.

If the lumber storage yard is not equipped with trackage the height of lumber piles should be limited to 18 or 20 feet with spaces between as ample as possible for ease in handling lumber to and from the piles and for access of fire fighting equipment in case of fire.

The receiving and handling of lumber should probably be given the greatest thought in providing transportation facilities to and from the plant, yet railroad sidings to the power plant for the delivery of machinery and coal, and to the shipping room for shipping the finished product, should receive careful consideration, keeping in mind that sidings to the lumber storage, power plant, and shipping room should have separate access to the main tracks, if

*Of Byron E. Parks & Son, Grand Rapids, Mich. An address delivered before the woodworking section of the eleventh annual National Safety Congress.



A furniture plant lay-out that is safe and efficient

possible, so that switching may be done on any siding without it being necessary to disturb the cars on any other.

Bulidings Designed for Their Intended Purpose

The type of buildings for any manufacturing plant should be carefully chosen to suit the purposes for which they are intended. In the past the purpose of a manufacturing building seemed to be little else than that of keeping out the weather and supporting the machinery and equipment inside. The modern manufacturing building must comply with several more requirements than those mentioned. A building should not only keep out the weather but should let in plenty of light and ventilation; it should not only just support the loads required of it but should do so with a proper margin of safety and as great an absence of vibration as possible; it should not only provide space for machinery, but should also provide ample space around machinery, with generous aisleways, in that greater efficiency in movement of materials and safety to employees will result; and, in short, it should be designed in advance for the work to be done—not simply built and then an attempt made to crowd in more machinery and equipment than the building will properly accommodate.

In order to comply with the above requirements, the building should be so designed that the glass area is a maximum with windows extending to the ceilings. Also to insure proper daylighting in the center, a building of the multi-storied type should not be over 50 to 60 feet wide.

It has been shown many times that excessive vibration not only causes rapid depreciation of machinery but also interferes materially with the quantity and quality of the product. Therefore, a building should be designed not only with considerations of strength in mind, but also rigidity and absence of deflection. If shafting and pulleys are used to transmit power, the floor structure should be laid out with this end in view, providing ample head room and substantial supporting members for shaft hangers and bearings.

Of the types of construction in use, the reinforced concrete building probably best complies with the above requirements of a good building, although a properly designed slow burning mill type makes a very satisfactory building and has one advantage over the reinforced concrete, in that machinery, shafting and equipment are more easily installed and alterations to machinery arrangement made.

Important Points of Machinery Layout

Much has been written concerning the layout of machinery in a woodworking plant to obtain efficient production and prevent accidents, consequently it will probably only be desirable at this time to emphasize some of the more important points to be kept in mind. In the first place machining should be carefully chosen for the work which it is desired to perform. Some machines are suitable for performing various operations, but wherever possible machines should be chosen for specific operations as it is often difficult to locate a machine performing several operations so as to obtain an efficient and orderly flow of material through the plant. It is also bad practice from a safety standpoint, as it is difficult if not impossible to design guards suitable for all the operations of which a machine is capable and if various guards are supplied suiting these various operations they must necessarily be of a temporary nature and are likely to be removed and not used.

It has also been my observation that machines which are provided with efficient guards by the manufacturers are more desirable than machines which have to have guards built by the purchaser. Homemade guards are frequently unsubstantial and do not entirely serve the purpose for which they are intended. Chain drive and gear guards in particular should be installed by the manufacturer, for they should preferably enclose the gear or chain drive completely. Such a guard not only serves to protect the workman but also materially affects the life of the machine by keeping dust and dirt from the bearings and other moving parts.

The Value of a Routing Chart

In laying out the machinery in a new machine room or re-arranging it in an old room, with the end in view of obtaining the most efficient layout, a routing chart should be drawn up. This routing chart should list each separate part entering into the finished product with the proposed volume of manufacture per unit of time. Such a routing chart giving the sequence of operations will establish in a general way the sequence or arrangement of the various tools and machines throughout the department.

A paper templet, to scale should be made of each article of equipment, such as all machines, tools, benches, racks, etc. Each templet should indicate the name of the machine or operation, the path of the product through the machine, the point of application of power, position of operator, and position of helper, if any. A floor plan of the machine room to the same scale as the templets should be prepared and then the templets placed on this plan and moved about and located in accordance with the routing chart until the most satisfactory arrangement is found, the marks on the templets allowing the machines to be set in proper relation to flow of product, power supply, lighting, etc.

Power Transmission

After an arrangement of the equipment has been completed a careful study should be made of how the product is to be transported from machine to machine, making ample provision for aisleways and location of trucks at machines to allow of efficient handling of material in and out of machines. Consideration should also be given to the necessity of providing spaces for accumulation of material between machines where the speed of handling varies.

The next important problem in laying out a machine room is to decide on the method of transmitting power to the various machines. There are in general two methods of driving machinery—shafting, pulleys, and belting and the electric drive. The electric drive may be further divided into two classes—the group drive and the individual drive. The decision as to which type of drive to use is dependent on several factors. In large plants with widely distributed machine rooms the electric individual or group drive is practically the only means of transmitting power efficiently and economically. In small and moderate sized plants the most efficient method of transmitting power is undoubtedly by means of line shafting, pulley and belts.

The transmission of power is one of the few features of a plant where safety and efficiency may seem to some antagonistic.

Electric transmission, properly designed and in-

stalled, is undoubtedly preferable from a safety standpoint to a multitude of pulleys and belts and possibly if proper statistics were available it could be shown that electric drive was the most efficient from the standpoint of cost when taking into consideration the fewer accidents resulting from the electric drive than from line shaft drive.

In any event the decision as to the proper method of transmitting power in any plant must be made upon a proper consideration of the various factors involved, the utmost safety and efficiency being kept in mind at all times. If line shaft drive be the final decision, it goes without saying that every means should be adopted for preventing accidents such as providing proper guards for belts and pulleys; using safety type set screws; cutting off projecting keys; covering up unused sections of keyways; and covering up or otherwise guarding all revolving parts which otherwise are likely to catch a man's clothing.

Another feature which will add materially to the safety of a line shaft installation is an automatic stop valve on the engine with electric tripping device. By locating push botton stations frequently throughout the plant, the engine and consequently all machinery may be stopped at a moment's notice and many accidents which would otherwise prove serious to both men and machinery be "nipped in the bud."

Safety in Electrical Installations

While, as pointed out above, the electrical transmission of power, when properly designed and installed, is better from the safety standpoint than line shaft drive, yet if poorly installed it may be more of a menace than pulleys and belting. In the first place all electric wiring in a woodworking plant should be installed in rigid metallic conduit. Open wiring is always dangerous to both men and plant and particularly so when inflammable dust may so easily be ingited by sparks. All motors of the direct current or slip ring alternating current type should be of the enclosed pattern in order to avoid danger from fire caused by sparks from the brushes. The squirrel cage induction motor may well be enclosed also to keep out accumulations of dust and dirt from the windings although the danger from sparks is not so prevalent as with the types above mentioned.

The motor starting equipment should also receive thoughtful study and all types of open switches and starters with exposed live parts avoided as one would the plague. Such equipment is a constant menace to both plant and men and should not be tolerated in this day and age.

Motors, unless connected direct to the machines which they drive, should be located overhead on suitable brackets or platforms and the platforms should be large enough in all cases so as to provide ample room for the repair man. Motor compensators or starters should be of the remote push button control type and should be located on the platform with the motor. This places them in a position where they cannot easily be tampered with and the only part of the equipment with which the workmen is concerned is the push button control station near his machine. Where group driving of machines is used it is advisable to use two or more push button control stations so that the motor for driving each group of machines may be started or stopped from several different points.

The remote push botton control starter is not only absolutely safe from the standpoint of the operator, but it also effects economies in the consumption of current for a workman has but to touch the "start" or "stop" button, as the case may be, instead of operating a clumsy compensator, or open switch, which he will avoid using as much as possible.

The Exhaust System

One of the important adjuncts to a woodworking plant is the exhaust system for the removal of shavings and sawdust from the various machines. If well designed it will pay large dividends in promoting the safety and comfort of employees, increasing production and making available for fuel a waste product that would otherwise be difficult and expensive to dispose of. Woodworking machinery produces large quantities of shavings and sawdust and if it is not removed as soon as it is made it soon accumulates on the machine, adding to the discomfort of, if not chance of accident to, the operator and necessitating frequent stops to clear away the refuse.

This refuse also forms a valuable fuel and if not delivered to the boilers by an efficient exhaust system it could not be fired in the furnaces without a great amount of labor being necessary to collect it and deliver it to the boiler room.

The exhaust should be carefully designed and installed and should fulfill the following requirements:

1. It should handle both light and heavy refuse satisfactorily.
2. The hoods should be designed where possible to also act as guards.
3. Hoods and piping should be laid out so as not to interfere with the operation of the machine, access to working parts, or obstruct the room.
4. It should be laid out to avoid danger of clogging and should have frequent clean-out openings through which to clear the system in case of clogging.
5. The exhauster should be selected striking the proper balance between first coat, power consumption, and power cost.
6. The separator should be ample in capacity so as to obtain efficient separation of the dust and deliver the refuse to the furnace with a minimum of excess air.

The advantages, in fact, necessity of a good exhaust system are generally so well understood that it does not seem necessary to more than mention the salient features here.

Better Illumination is Needed

Artificial illumination has been given very little thought and study in the majority of woodworking plants which I have observed. In a large plant which I visited recently they were still using gas lights in one of the machine rooms, although the remainder of the plant is lighted with electricity. It hardly seems necessary to state that gas lighting has no place in woodworking plant, particularly where electricity is available.

Even where plants are lighted with electricity the prevalent system, if system it can be called, consists of a drop cord and bare lamp over each machine or bench with a few thrown in for general illumination. Good illumination will add so tremendously to the safety and efficiency of a manufacturing plant that arguments in its favor seem almost superfluous. "Spotted" fixtures over machines are often advisable but at the same time the general illumination ought to be sufficiently brilliant so that men can see to get

around without stumbling over objects on the floor and so that production may be maintained with artificial illumination at the same rate as with daylight. There are many efficient lighting fixtures and reflectors, at reasonable cost, on the market today and a well laid out lighting system augmented by ceilings and walls painted a light color will pay dividends in increased production and decreased accidents, which will surprise any executive still adhering to antiquated methods.

Other features adding materially to the safety and efficiency of the plant, such as adequate fire protection, proper heating and ventilating, satisfactory elevating and conveying machinery suited to the needs of the plant, etc., might be dwelt on at length but can hardly be treated with the brief scope of this paper. In closing I wish to once more remind my hearers that as a general proposition whatever is done to promote the efficiency of a manufacturing plant will likewise promote the safety of the employees and any measures to promote safety will bring substantial returns in increased efficiency.

Dry Kiln Capacity Increased by an Improved System of Piling

Piping and Stacking Rearrangements Take the Fullest Advantage of the Natural Tendency of Hot Air to Rise—Stagnant Zones Eliminated and Rapidity of Circulation Increased

By A. M. Smith*

Mill operators are beginning to realize that drying lumber by artificial means does not pay where this is being attempted with the hit and miss method too often used, and the responsibility is being placed more and more in the hands of operators specially trained for the job. Existing kiln equipment has been analyzed, found wanting and remodelled to increase its capacity, or, where a new plant has been decided on much thought and investigation has been given to the different methods before letting contracts or buiding new equipment.

Nearly all existing kilns are built on the assumption that the hot air will rise through the lumber. The heating coils are accordingly placed in the building so that they will be beneath the load of lumber, as in Fig. 1, which shows a double track kiln 100 x 20 feet. A little consideration will convince the reader that improvements can easily be made in this arrangement.

The air passing over the heating coils at "A" rises upward and enters the load of lumber, but as soon as it does enter the lumber it begins to cool and becomes saturated and of course, since it is no longer hot air, ceases to rise and passes out at the sides as shown by the arrows. It will be readily understood that progressive drying takes place, the bottom boards having to dry considerably before the air can rise to the upper portions of the load. Some circulation is secured near the top due to the column of hot air rising from the piping in the centre between the cars, but it has been found that there is a stagnant portion as enclosed by the irregular line "B" which is last in drying, thus necessitating the whole load being kept in the kiln until this portion is dry.

*Chief engineer, Vancouver Lumber Co.

Rapid Circulation is Necessary

Everyone having anything to do with drying lumber knows that case hardening and checking are caused mostly by too dry a condition of the air in the kiln, that is, too low humidity, and one of the essentials of the operator is a hygrodeik, or wet and dry bulb thermometer. Although heat is the factor which does the drying, high temperature is not as necessary as a rapid circulation of air over each board; in fact, the more rapid the circulation and the less the difference between the wet and dry bulb temperatures compatible with reasonable speed, the better the drying so far as degrade is concerned. This can be accomplish-

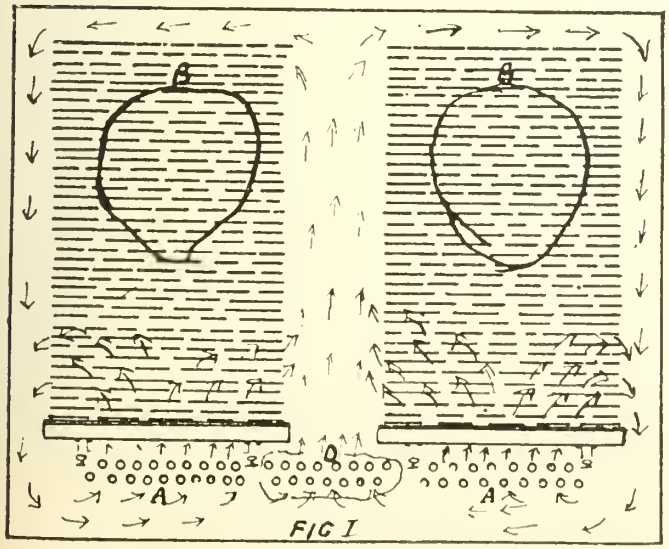


Fig. 1—Shows how areas of stagnation make for inefficient drying

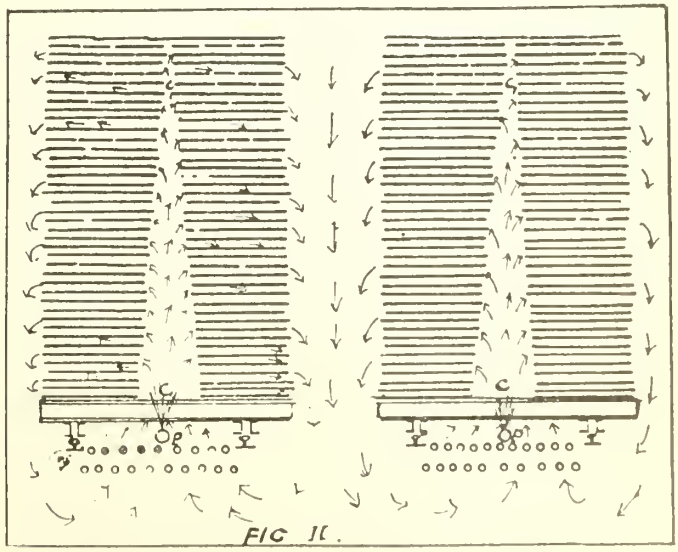

Fig. 2—Rearrangement of pile and piping facilitates circulation

ed in various ways. In some systems a fan is used to circulate the air in the kiln. This, of course, presupposes a charge kiln and is not very suitable for a progressive type of kiln, as the fan, in drawing the air from the lumber, mixes the air of high humidity with that from the dry end and of low humidity and in discharging the air again to the lumber does so at a uniform degree of saturation, making the wet end too dry, or the dry end too wet for good operation. It also entails the first cost of motors or engines to drive the fans, together with their belts, bearings, etc., and the maintenance of same.

Rearrangement of Kiln

Kilns can be arranged, however, that will take the fullest advantage of the natural tendency of hot air to rise and in which the steam necessary to maintain proper humidity is utilized to augment the natural circulation. The writer has made several changes in the "Standard" kilns with a view to increasing their capacity. At the present time we are using the system shown in Fig. 2, piling the lumber on the car

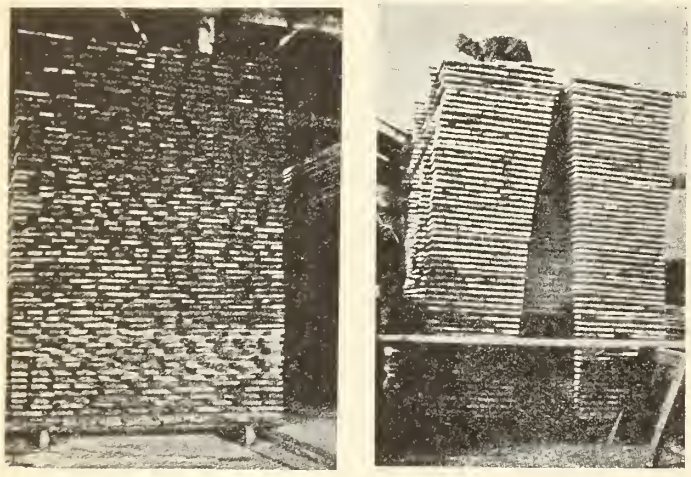

Fig. 3—The old and new piling methods

being the most important feature of the whole. The middle coil D, Fig. 1, has been done away with and in this case hot air rises as there is nothing to reduce the temperature of the air until it enters the layers of boards and we have the same temperature at the top of the load in the inverted "V" at c, as we have at the opening of the "V" at c.

The steam jets shown at P consist of a 1¼" pipe, which extends from the door at the wet end to within ten feet of the dry end. This pipe is perforated every 14" by a 1/16" hole and a pressure of about 40 lbs. is maintained on this pipe. The movement given to the column of air in the "V" is considerable. If the edges of the pile in the "V" are straight, as shown in the photo, the large amount of hot air entering at the bottom of the "V" is distributed evenly over each layer of boards; thus the top, middle and bottom parts of the load are drying uniformly. Notice also that the air has only to pass over 30 to 34" of board surface before returning to the heating coils, thus reducing the lay of the outside boards to a minimum.

Temperature Records

The following table shows the average temperature taken for a car of 1" lumber as it progresses through the kiln. A series of four readings were taken for each position of the car, the first being taken two hours after the car had been placed in the kiln and the others immediately after each move forward. A fresh car was run in at 7 a.m. and at 5.30 p.m. each day, making six moves before the car was drawn from the kiln, a total of 72 hours drying time. While as large a difference as 40 degrees F. was observed in the readings at some of the positions, the average shows that this is about as near progressive as could be desired:

	Temp. at "A".		Temp. at "C".	
	Dry	Wet	Dry	Wet
(1)	154	146	142	140
(2)	170	158	151	145
(3)	184	152	152	138
(4)	184	136	161	132
(5)	186	136	165	131
(6)	190	132	183	132

The kiln in which this load was dried had the fresh air shutter open 12" or 1 square foot. An anemometer gave a velocity of 1,639 ft. per minute, or a movement of air through the kiln of 1,639 cubic feet per minute.

Six hours after placing a load in this kiln the temperature of the entering air ten feet from the opening and after passing over the heating coil was 192 degrees F. dry bulb and 146 degrees F. wet bulb. The leaving air near the stacks and at the door at the wet end was 162 degrees F. dry bulb and 158 degrees F. wet bulb, or an entering humidity of 26% corresponding to 57 grains of water per cubic foot; leaving humidity 88% or 80 grains per cubic foot, or the amount of water carried off by the air passing through equalled (80—57) x 1,639 or 37,697 grains per minute, or 6.5 lbs. per minute or 380 lbs. per hour, or a total of 72 x 380=27,360 lbs. The kiln contains fifty thousand feet of lumber and taking the kiln dry weight to be 2,000 lbs. to the M, the total weight in kiln is 50 x 2,000 or 100,000 lbs. Taking the average moisture content to be ⅓ of the total weight, the amount of water to be removed will be about 30,000 lbs. which comes very close to the weight of water carried off by the air passing through the kiln.

Regeneration of the Air

It must not be assumed that it is necessary to have this amount, or any amount, of air passing through the kiln to accomplish the drying, as the air in the kiln can be regenerated or made capable of absorbing moisture by cooling and reheating; in fact, part of the drying in our case is done by the cooling effect of the side walls and the floor of the kiln. If the air leaving the lumber is near saturation or 100% humidity and becomes further cooled on passing down the sides of the building and in the comparatively cold part under the piping, it will drop a portion of its load of water on the floor. The air on again passing over the heating coils is made capable of absorbing more moisture. Where a closed system can be used and where only the leakage through doors and walls is lost, the steam consumption per M feet of lumber dried is of course somewhat less than in the ventilated system, where a large amount of heat is lost through the ventilators, as the gases passing out are never fully saturated.

A steam flow meter, on the kiln mentioned above, with an average load of 55 M feet in the kiln, shows a steam flow of 3,421.7 lbs. of steam per hour, or 62.2 lbs. of steam per hour per M—1.8 h.p. per hour per M. While this seems to be high, it will be found that this is about the proper allowance to make for drying lumber in any type of kiln.

Check Drying Operations Very Closely

If You do not Want to Lose Your Whole Kiln Load, Make Frequent Tests and Regulate the Drying Accordingly—Condition of the Stock is the Governing Factor

In the July "Canadian Woodworker" mention was made of the suggestion that too much attention is often given to the moisture content of the stock to the exclusion of other phases of the drying operation and the broader definition of what constitutes well dried lumber. While there was more or less truth in the ideas advanced and considerable justification for the suggestions made, yet the fact remains that the moisture content of the stock all through the drying operation is the very heart of kiln drying as practiced today and it is only through a close check on the moisture content of the charge, and a knowledge of the significance of moisture changes, that we can hope to dry lumber with a minimum drying loss and dry it so that it will be reasonably free from strain and stresses.

This, however, might best be illustrated by an outline of an actual occurrence in a well known furniture plant. The kiln was filled with two inch gum, which had previously been tested for moisture content. The kiln was closed and the stock was subjected to live steam for a number of hours. After the steaming period, the conditions in the kiln, that is, the humidity and circulation, were regulated so as to conform to the moisture content of the stock as shown by the tests made when the lumber was placed in the kiln and the run continued. After the stock was taken out it was found to be so badly checked and honey-combed as to be absolutely useless and could only be used for firewood. Now, then, where did the methods outlined fall down?

Condition of the Stock is Governing Factor

It is known and generally accepted that the condition of the stock, not time, is the controlling factor in drying lumber in a kiln and that at all times the humidity and temperature should be regulated in accordance or to put it another way, the E.M.C. (equilibrium moisture content) of conditions in the kiln should be maintained at a point slightly below that which actually obtains in the lumber. If the difference is too great, checking, case-hardening and honeycombing is likely to occur, while if the variation is not sufficiently marked, the rate of drying will be retarded.

In the case in point, the important fact that was overlooked was that steaming raises the moisture content. While the stock may have tested 15 per cent when placed in the kiln after being steamed for eight or ten hours the moisture content might be found to be 25 or even 30 per cent. Overlooking this increase in moisture content and regulating conditions to suit stock of 15 per cent and then making changes on a time schedule, that is, raising the temperature and lowering the humidity every twelve or twenty four hours, would mean that unusually secure conditions would maintain all through the drying period and as a consequence the lumber be damaged. This is evidently what happened and the result was a total loss of the whole kiln load of lumber.

The proper way is to make frequent tests all during the drying operation, and operate and regulate the kiln accordingly. This may entail extra work but it is the only basis upon which a kiln can be operated intelligently. There is no other way. It is all very well to raise the temperature five points and drop the humidity five points ever so often, say every twenty-four hours, but in doing that there is no guarantee that the condition of the lumber warranted the change or that it did not warrant it much sooner. The faster the rate of drying, the harder the drying is being pushed, the greater the need for testing frequently and regulating accordingly.

Make Frequent Tests

Slip-shod, hit-or-miss methods should not be tolerated in connection with the operation of the dry-kiln, for there is too much at stake. Not only is there the danger of spoiling the lumber during the drying period, but unless the stock is properly dried there is sure to be trouble later on. The proper operation of the dry kiln is so important that it is not an exaggeration to consider it the key operation in the whole manufacturing process. This feature of frequent tests should be emphasized for it is the only way of knowing how the drying is progressing. More than that, by testing the centre and outside of the samples separately the variation in moisture content will serve as a warning if it becomes too marked. A considerable variation between centre and surface indicates a tendency toward case-hardening if it does not show that case-hardening has already occurred. This merely serves to indicate how frequent tests assist in maintaining a close check on the drying operation.

Self Server is a New Wooden Novelty

The Canada Toy & Novelty Manufacturing Co., of Smith Falls, Ont., which began operations about a year ago, is perfecting a number of lines which will soon be placed on the market. One of the novelties which is being featured at the present time is a self-server. This device which sits on the centre of any table—is supported by a three-legged stand on which the top section is attached through a steel pivot, so that the server rotates freely. The stand is also detachable from the top section for conveniences.

The top is made from basswood, cypress, cedar, oak or any other suitable wood, eighteen inches in diameter with a round edge. The self-server is designed to hold pepper, salt, sugar, pickles, sauces, cheese, bread and other requisites found from day to day in the family fare. The self-server, of course, implies that the constant passing and repassing of these articles is rendered unnecessary by the fact that each person turns the self-server and helps himself to whatever he may desire.

If you are running a large mill, either by gas, steam or electricity, remember that you should have a variety of oils, heavy, medium and light, each for their particular purpose. A heavy cylinder oil will clog the running of a spindle.

Why Should Costs Vary by 73 Per Cent?

Estimates of the Cost of a Table and Two Benches Range from $37.13 to $64.81, While the Amount of Material Is Guessed to Be Anywhere from 94 feet b. m. to 148 feet—Obviously Something Wrong

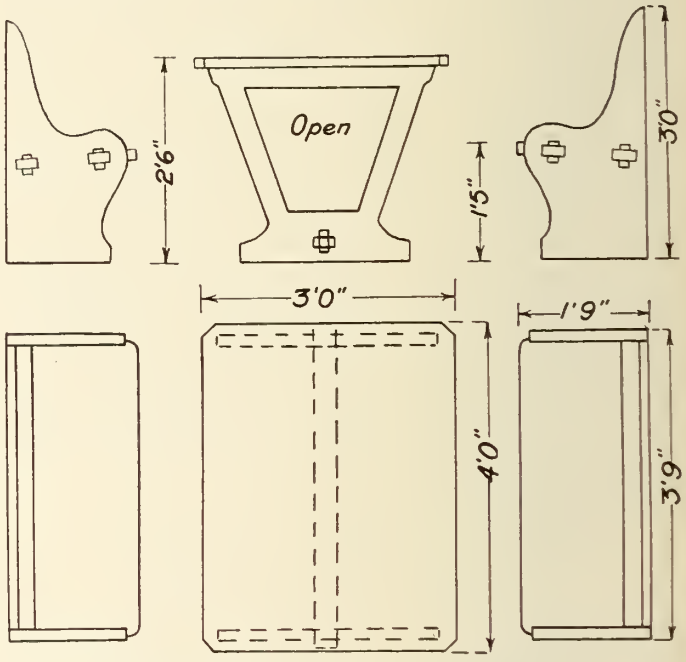
Subscribers in submitting cost figures for these articles which have been appearing month by month almost invariably commend our efforts in this direction and urge us to continue our policy of a monthly cost study. These words of commendation indicate that some at least of the woodworkers appreciate the object we had in mind when inaugurating this series. They, apparently, recognize, as we do, the fact that estimating procedure in the woodworking industry is not on the right basis. We are sure that even those who did not feel that there was much wrong with their estimating practice have, after studying the articles in the past few months, come to realize that there is something seriously wrong when estimated costs vary by the large percentage that are evident in the figures we print. In many instances the costs of the same article have varied almost as much as 100 per cent.

It was just to show up these facts that this series was started, in addition to which, of course, we had in mind the spreading of a little propaganda directed toward the solution of this guesswork procedure. It is quite evident that there must be something wrong when estimates vary by a large percentage. Either the low bidders are losing money or the high ones are making an excess profit or are operating at too high a cost. Making all due allowance for differences in conditions pertaining at different woodworking plants, there should not be the wide variation evident in many of the studies that we have published in the past few issues. If woodworkers as a whole would take to heart the lessons we wish to teach in these studies, they would make more effort to determine their exact costs on various operations and keep this information on tap for use in submitting estimates on new work. One prime object of every management of a woodworking plant is to do the work at the lowest cost—consistent with quality, of course—but whatever the cost may be, whether it is as low as it should be, the articles must be sold at a figure somewhat above the cost, if a profit is to be made. It is, therefore, essential that the true cost of every article and operation be known so that the selling policy can be arranged to net a profit on the firm's books. To this end there should be no guess-estimating, no haphazard or slapdash figuring. On the other hand every estimate should be the subject of a careful analysis of plant operations and methods so that the figure obtained may be considered as a reasonable expectation of what the cost of that particular article will be.

The wide discrepancy in estimated costs that has just been spoken of, is again evident in the cost study for this month—a breakfast room set comprising table and two benches, as detailed in the accompanying sketch. The list of figures given herewith briefly summarizes the forecasts of cost submitted by nine woodworking firms. It will be seen that these estimates vary all the way from $37.13 to $64.81, a variation of 73 per cent. Now it is evident that even making due allowances for the different conditions pertaining in different woodworking plants, most of these figures are away out. Either the low men will lose out on handling this job or the high ones will make too great a profit or their costs are too high and need some readjustment.

It is when we come to analyze the various factors involved in these estimates, however, that we see to what a dangerous extent these discrepancies work out. Take material, for example. One firm figured that 94 feet, b.m., were necessary for this job; another 95 feet; another 110 feet, and so on up to 148 feet. There is no reason on earth for such a wide variation in the estimated amount of material going into a comparatively simple job as this. Five or ten per cent ought to express at the most the difference between the high and low figures, but in this case we have nearly

This is the Job —



And these are the figures.

Where do you stand?

No.	Material	Waste	Bench hrs.	Rate	Machine hrs	Rate	Commercial Burden	Total
1	$ 7.52	20%	20	$ .85	6	$1.07	20%	$37.13
2	5.74	7%	34	.60	3½	1.50	20%	37.67
3	9.54	15%	21	.80	6	1.10	25%	41.18
4	10.20	10%	25	.92	7	1.15	15%	47.73
5	17.50	25%	16	1.00	8	1.25	15%	50.00
6	12.21	15%	33½	.88	6½	1.04	15%	55.73
7	11.61	20%	34	.85	6½	1.50	20%	60.34
8	11.47	15%	33.6	1.00	6.4	1.17	20%	63.07
9	14.10	20%	28	1.00	7½	1.30	25%	64.81

60 per cent—certainly far too much, and sufficient to indicate that millmen need some training in the matter of taking off quantities. Strictly speaking, the net quantities of material should be the same in every instance, the only difference being in the calculated amount of waste, and on this factor there should not be very much difference. The importance of the waste factor was emphasized in our last issue, this being governed by the grade of lumber bought or available and the availability of opportunities to use what would otherwise be waste. In the figures submitted to us this month the various estimaters calculate the waste at anywhere from 7 to 25 per cent. If one man can keep his waste down to 7%, then those others who waste one-quarter of their stock should give serious consideration to some means for eliminating or using up waste material. It is evident that the mill who can operate on a 7% waste basis is going to be more money in pocket than that which must consider a 25% wastage.

The estimated amount of labor and machine time involved in making this breakfast room set can be criticized in a similar way. The number of bench hours varies all the way from 16 to 34, with the latter figure, or something approaching it, involved in four of the nine cases. Machine hours spread from 3½ to 8 with 6 to 6½ predominating. Of course all shops do not handle a job of this character in exactly the same way, but we fear that many estimaters do not make a proper analysis of the labor involved in manufacturing these articles.

It will be interesting for the subscribers who have been good enough to supply figures, to compare their estimates with that of the Millwork Cost Bureau, whose estimate is given in the accompanying table as No. 8. In detail their figure is obtained as follows:—

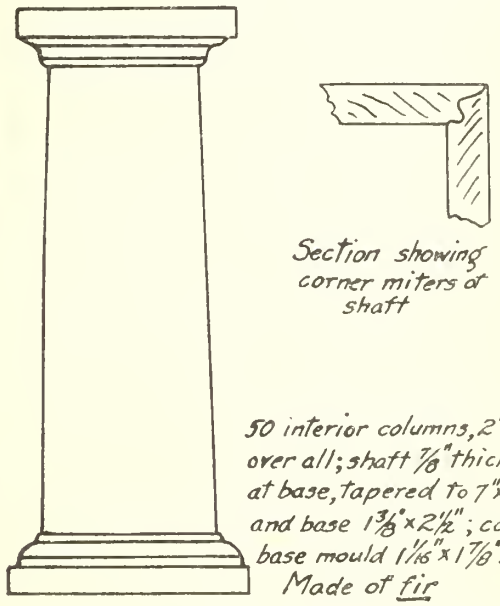
Material, delivered purchase price	$72.00		
Lumber burden	5.30		
Without waste	77.30		
Waste 15%	11.60		
129 net board feet @	88.90		11.47
Machine			
Labor 6.40 hours @	.60	3.84	
Burden 6.40 hours @	.57	3.65	7.49
Bench			
Labor 33.60 hours @	.66	22.18	
Burden 33.60 hours @	.34	11.42	33.60
Factory Cost			52.56
Commercial burden 20%			10.51
Total Cost			$63.07

The Millwork Cost Bureau, of course, bases its material prices at rates representing the Chicago market, but its wages and burdens are at rates representing an average of the entire membership. The total costs thus obtained are average costs, and if calculated on the basis of your own rates to reflect your own conditions, should give your cost of handling this work. With the number of machine hours and bench hours, determined by the Millwork Cost Bureau as necessary for the handling of this breakfast room set, there are two of our subscribers, Nos. 6 and 7, who practically agree. Some of the others are not so very far out, while there are one or two whose estimates are in no way comparable.

If our subscribers will just analyze these figures as they appear from month to month, they will see in what a bad condition estimating is. They will then realize that the good of the woodworking industry demands more careful costing and will do their part toward attaining this end. We urge that they help us in our efforts to further this object by sending us in their ideas on cost and by commenting on anything we may say in this connection.

For next month we have selected a comparatively simple job—an order for 50 columns of the type indicated in the accompanying sketch. These will be 2 feet, 3 inches high, over all, with a shaft ⅞ inches thick, measuring 8 x 8 inches at the base and tapering to 7 x 7 inches at the cap. We will consider them to be made of fir and produced in an odd work factory. Will not our readers take their pencils in hand and figure out just what they could handle this order for? Let us try to get an unusually large number of figures in the October issue so that the lessons to be learned from this study will be all the more evident.

Figure This Out for October



Section showing corner miters at shaft
50 interior columns, 2'3" high over all; shaft ⅞" thick, 8"x8" at base, tapered to 7"x7"; cap and base 1⅜"x2½"; cap and base mould 1 1/16"x1⅞". Made of fir

Let us see if we can't get down to real estimating this time. Send in your figures, so that in the next issue we may have a representative list of estimates for comparison.

Upholstered Furniture Association

The next mass meeting of the National Association of Upholstered Furniture Manufacturers will be held at Signal Mountain Hotel, Chattanooga, Tenn., October 10, 11 and 12. The tenth will be devoted to a meeting of the executive committee, on the eleventh the semi-annual meeting will be held, and on the twelfth the davenport bed makers will convene.

Edmonton Upholsterers Change Address

The Thornton-Perkins Co., upholsterers and cabinet makers, have removed from 10753 Jasper Avenue, Edmonton, Alta., to more commodious premises at 10628 Jasper Avenue.

Revised Standards for Wooden Boxes

In the New Draft of the A.S.T.M. Regulations, the Most Important Change is the Addition of a Rule for the Strapping of Boxes and the Reduction of Lumber Thickness When Strapping is Used

Numerous slight changes and a few more important ones are noted in the latest revision of the general specifications for wooden boxes, nailed and locked-corner construction, adopted by the American Society for Testing Materials, at its recent annual meeting. The committee of this organization, which has been aiming to formulate standards for shipping containers, has been working in close co-operation with other bodies having the same object in view, notably the National Association of Box Manufacturers, American Railway Association, the Freight Container Bureau, a subsidiary of the Bureau of Explosives of the United States, and the Forest Products Laboratory, Madison, Wis. The chairman and secretary of the committee of the American Society for Testing Materials are both connected with the Forest Products Laboratory.

While the revised specification is not final, it, at least, marks an important step forward toward the acceptance of standard regulations governing the manufacture of containers. The first draught was published in the "Canadian Woodworker" of September 1920, and while many of the clauses contained in the present specification, are similar, they are again reprinted in order to show their relationship to the whole specification. The most important change offered in the revised draught is the addition of a rule for the strapping of boxes (Section 15) and for the permissible reduction in thickness of lumber when strapping is used (Section 16). It is to be emphasized that the inclusion of these strapping rules does not mean that all boxes moving in transportation must be strapped, but that when strapped boxes are required, these regulations should govern. These regulations must be tentative for the present because regulations governing the use of round metal strapping, which are not yet drawn up, are needed to make them complete. When detailed specifications for unstrapped boxes are prescribed, strapped nailed boxes with thinner sides, tops and bottoms may be used.

The specifications as revised are as follows:—

1. These specifications are intended to apply to wooden boxes of nailed and lock-corner construction, and are directly applicable to the styles of boxes illustrated on page 64 of the July "Canadian Woodworker."

I. Material

2. The parts shall be made from thoroughly seasoned lumber. Under average conditions, thoroughly seasoned lumber has a moisture content of 12 to 18 per cent of the weight of the wood after oven drying to a constant weight.

3. All defects in the lumber that materially lessen the strength of the part, expose the contents to damage, or interfere with the prescribed nailing, shall be eliminated.

4. Ends, sides, tops, bottoms and other parts of a box shall be well manufactured and cut true to size.

II. Grouping of Woods

5. The principal woods used for boxes are classed for the purpose of specifications into four groups, as follows:

Group I: White pine, Norway pine, aspen (popple), spruce, western (yellow) pine, cottonwood, yellow poplar, balsam fir, chestnut, sugar pine, cypress, basswood, willow, noble fir, magnolia, buckeye, white fir, cedar, redwood, butternut, cucumber, alpine fir, lodgepole pine and jack pine.

Group II: Southern yellow pine, hemlock, North Carolina pine, douglas fir and larch (Tamarack).

Group III: White elm, red gum, sycamore, pumpkin ash, black ash, black gum, tupelo and maple, soft or silver.

Group IV: Hard maple, beech, oak, hackberry, birch, rock elm, white ash and hickory.

III. Dimensions of Parts

6. (a) The thickness called for in specifications for boxes of any given commodity will, unless otherwise specified, be understood as applying to woods of groups I and II.

(b) When the thickness of material in the following table are specified (for groups I and II woods), woods of groups III and IV may be used with the following permissible reduction in thickness:

Specified Thickness of Parts (Group I and II).	Allowable Reduction in Thickness for Groups III and IV.
¼ to ½ in., incl.	1/16 in.
Over ½ to 1 in., incl.	1/8 in.
1 to 2 in., incl.	1/4 in.

7. The occasional variation below the thickness of parts specified in Section 6 shall not exceed one-eighth of the thickness of the part.

8. (a) The maximum number of pieces allowed in any side, top, bottom or end of a box shall be as follows:

Width of Part.	Maximum Number of Pieces.
4 in. and under	1
Over 4 to 7 in., incl.	2
" 7 to 10 in., incl.	3

Over 10 in. shall average not more than one piece for each 3 in. of width and no piece shall be less than 2½ in. in width. Boards matched and fastened as provided in the following section may be not less than 1½ in. in width at either end.

(b) Two or more pieces ½ in. or over in thickness, fastened as follows shall be considered one piece in sides, tops and bottoms: butt-jointed or matched and fastened with two or more corrugated fasteners 1⅛ in. in length and of sufficient width to penetrate approximately three-fourths the thickness of the material.

IV. Manufacture of Boxes

9. The outside surface of boxes shall be sufficiently smooth to permit of legible marking. When surfacing of boards two sides is necessary for the protection of the commodities in transportation. The material may be 1/32 in. thinner than the minimum specified.

10. (a) Ends ⅞ in. or less in thickness, if made

of two or more pieces, shall be: (1) butt-jointed or matched, and fastened with two or more corrugated fasteners; or (2) cleated.

(b) The sizes of corrugated fasteners used shall be as follows:

Thickness of end, in	Size of fastener, in
3/8	1/4 by 1-1/8
7/16, 1/2 and 9/16	3/8 by 1-1/8
5/8, 11/16 and 3/4	1/2 by 1-1/8
13/16 and 7/8	5/8 by 1-1/8

(c) The number of fasteners used shall be as follows:

Length of End.	Number of Fasteners
16 in. and under	2
Over 16 to 24 in.	3
" 24 to 26 in.	4

(d) When three or more fasteners are required, they shall be driven alternatively from opposite sides of the end.

(e) Two or more pieces Linderman jointed shall be considered one piece.

Schedule of Nailing

11. (a) All nails shall be standard cement-coated box nails of the following length and gage (Washburn and Moen or American Steel and Wire Co. gage):

Size of Nails, "Penny."	Length.	Gage No.
2	1 in.	16
3	1⅛ "	15½
4	1¼ "	14
5	1⅝ "	13½
6	1⅞ "	13
7	2⅛ "	12½
8	2⅜ "	11½
9	2⅝ "	11½

(b) If other than cement-coated nails are used, 25 per cent more nails shall be driven than specified for cement coated nails. Plain nails driven through and clinched may be used for cleating.

12. The size of nails to be used is determined by the species and thickness of the material in which the points of the nails are held, and shall be in accordance with the following table:

Size of Cement-Coated Nails for Different Species and Thickness of Material

Species of Wood Holding Nails.	Thickness of Ends or Cleats to Which Sides, Tops and Bottoms are Nailed, in.								Thickness of Sides to Which Top and Bottom are Nailed, in.		
	⅜ or less	7/16	½	9/16	¾	11/16 or ¼	13/16	⅞	Less than ½	½ to 9/16	5/8 to ⅞
Group I woods	4	5	5	6	7	8	8	9	4	6	7
Group II woods	4	4	5	5	6	7	7	8	4	5	6
Group III woods	3	4	4	5	5	6	7	7	3	4	5
Group IV woods	3	3	4	4	4	5	6	7	3	4	5

NOTE.—If the designated penny of nail is not available, the next lower penny shall be used, and the nails spaced proportionately closer.

13. (a) The spacing of nails holding the side, top or bottom to the ends of a box shall be as follows:

Size of Nails, "Penny."	Space When Driven into Side Grain of End.	Space When Driven into End Grain of End.
6 or less	2 in.	1¾ in.
7	2¼ "	2 "
8	2½ "	2¼ "
9	2¾ "	2½ "
10	3 "	2¾ "

(In order to ascertain the number of nails to be used, divide the width of the side, top or bottom (or length of cleat) by the spacing specified for the size of nails to be used. Fractions in the result greater than ¼ if the points of nails are to be held in the end grain, and greater than ½ if the points of nails are to be held in the side grain, will be considered as a whole number.)

(b) When side nailing is used the spacing of nails holding top and bottom to sides shall be 6 to 8 in. When the material in the sides is less than ½ in. in thickness, side nails shall not be used, unless otherwise specified.

(c) No boards shall have less than two nails at each nailing end, except boards less than 2½ in. in width, which are butt-jointed or matched and fastened with corrugated fasteners as specified in Section 8 (b) may have only one nail. When cleats of the thickness of the ends are used, the nails shall be driven in the ends and cleats alternately.

(d) When box ends are cleated, the spacing of nails holding cleats and ends together shall be the same as the spacing of the nails holding the adjacent side, top, or bottom to the end. Each piece of the end shall be nailed to each cleat with not less than two nails, except that end boards less than 2½ in. in width which are butt-jointed or matched and fastened with corrugated fasteners as provided for in section 8 (b) may have only one nail.

(e) Nails attaching cleats to ends shall be of sufficient length to penetrate both thickness of lumber and allow for clinching. Either cement-coated or plain nails may be used.

(f) When cleats are thicker than the ends, nails shall be driven through the end boards into the cleats and clinched.

14. Nails shall be driven flush. Over-driving of nails materially weakens the container.

V. Strapping of Boxes

15. When boxes are specified with flat metal straps, either (1) unannealed straps without nails or (2) annealed or unannealed straps nailed on, shall be used,

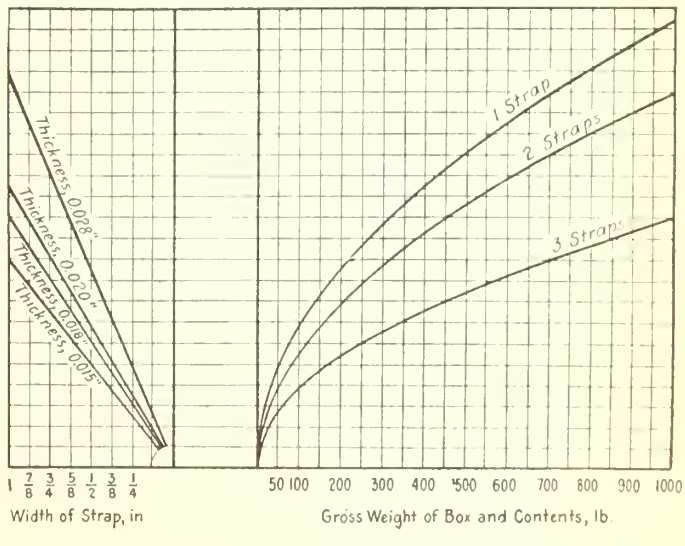


Fig. 1—Chart for Determining Size of Strap
Starting with weight of box and contents move directly upward to the curve for the number of straps to be used, then move to the left until intersecting the line representing the thickness of the strap to be used. The first vertical line at or beyond this point of intersection represents the width of strap required.

subject to the following requirements:

(a) When the straps are nailed on, they shall be placed around the ends of the box and held in position by the same size nails spaced twice the distance speci-

fied for holding the box parts together.

(b) Metal fasteners used to hold the ends of nailless straps together shall have not less than 75 per cent of the tensile strength of the strap.

(c) All straps shall be drawn so as to sink into the corners of the box.

(d) When two or three nailless straps are used, one shall be placed approximately one-sixth of the length of the box from each end.

(e) Fig. 1 gives the size of straps to be used on various gross weights of boxes. Starting with the weight of box and contents, move directly upward to the curve for the number of straps decided upon; then move to the left to an intersection with the line representing the thickness of straps to be used. The first vertical line at or beyond this point of intersection represents the width of strap required.

16. The thickness specified for sides, tops, and bottoms of unstrapped nailed boxes may be reduced to the thickness indicated below, when metal straps are used:

7/8	5/8	1/2
13/16	5/8	1/2
5/8	1/2	3/8
9/16	7/16	5/16
1/2	3/8	5/16
7/16	5/16	1/4
3/8	5/16	1/4

Rigid Crate Construction

Diagonal Bracing on Six Sides Gives Maximum Rigidity for Minimum Amount of Lumber

One of the features of a good crate is rigidity or ability to resist weaving and skewing during transportation. No method of joining the corner members of a crate, not even the 3-way corner construction, is sufficient alone to give rigidity to a crate. Some kind of bracing across the faces is usually necessary.

Figure 1 shows a kind of bracing found in many crates which are sent to the U. S. Forest Products Laboratory, Madison, Wisconsin, for testing. Partly because of the amount of material used, this construction appears to be very strong. Laboratory tests have shown, however, that crates so braced are weak in the diagonal direction of the faces, and are therefore apt to weave and skew during transportation.

Diagonal braces on six sides as shown in Figure 2 have been found to give a crate maximum rigidity for a minimum amount of lumber. Crates so braced withstood with considerably less distortion twice as great a diagonal compressive force in actual tests as crates braced as shown n figure 1.

A Combination of diagonal and parallel slat bracing as shown in figure 3, makes the crate more rigid than parallel bracing alone but not so rigid in all directions as cross bracing on the six sides. It may be found an advantageous construction in packing contents which need protection on the sides and are rigid enough themselves to withstand stresses in the direction in which the crate is weak.

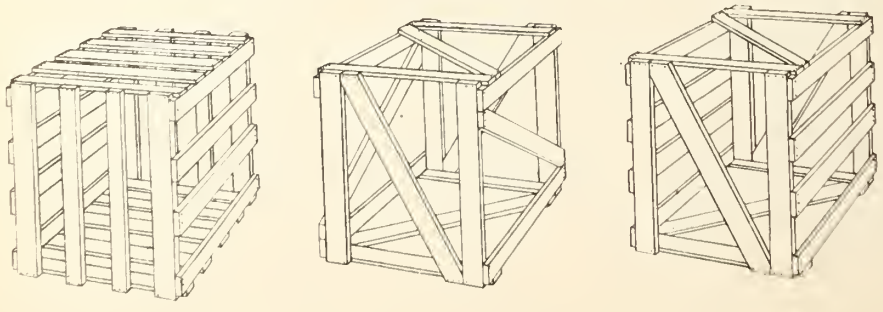
Solid sheathing on all the faces does not make a crate so rigid as diagonal bracing, except perhaps sheathing which is made of wide boards with tighter joints than can usually be obtained. The crate with ordinary sheathing might withstand as great a load, but the distortion caused by that load would be greater than in a crate with diagonal braces, and would ordinarily be great enough to allow damage to the contents.

Comparative Strength of Air-Dried and Kiln Dried Wood

Some wood users claim that kiln-dried wood is brash and not equal in strength to wood that is air-dried. Others advance figures purporting to show that kiln-dried wood is much stronger than air-dried. But some 150,000 comparative strength tests, made by the Forest Products Laboratory, of the U. S. Forest Service, on kiln-dried and air-dried specimens of 28 common species of wood show that good kiln drying and good air-drying have the same effect upon the strength of wood.

Tht belief that kiln drying produces stronger wood than air drying is usually the result of failure to consider differences in moisture content. The moisture content of wood on leaving the kiln is generally from 2 to 6 per cent. lower than that of thoroughly air-dried stock. Since wood rapidly increases in strength with loss of moisture, higher strength values may be obtained from kiln-dried than from air-dried wood. Such a difference in strength has no significance, since in use a piect of wood will come to practically the same moisture condition whether it is kiln-dried or air-dried.

It must be emphasized that the appearance of the dried wood is not a reliable criterion of the effect the drying process has had upon its strength. The strength properties may be seriously injured without visible damage to the wood. Also, it has been found that the same kiln-drying process can not be applied with equal success to all species. To insure uninjured kiln-dried material a knowledge of the correct kiln conditions to use with stock of a given species, grade, and thickness, and a record showing that no more severe treatment has been employed, are necessary.



The middle crate is the most rigid of the three. The left hand crate possesses very little rigidity.

Machinery & Equipment

A Glue Pot with Automatic Heat Control

Almost all of our readers at some time or other have had difficulty in using glue because of the great variance in the flexibility of glue mainly due to uneven heating. Glue, like most other similar substances has a certain point of temperature where it attains its greatest flexibility and viscosity. To secure this, thermostatic heat control has been recommended but there has been difficulty in producing a satisfactory, controlled heat, glue pot which is fully automatic and requires no personal attention.

To fill these requirements, the Wallace bench glue pot, here illustrated, equipped with a reliable, fully automatic heat control device, has been produced. There are several exceedingly practical and interesting features incorporated in this new glue pot the foremost of which is of course the automatic heat control which keeps the temperature of the glue between 140 and 150 degrees at all times.

There is a tube immediately above the heating element containing a sensitive volatile substance which contracts and expands with the slightest change in temperature and provides a dependable action of ample power to actuate the control switch. When the heat reaches the proper temperature the control turns off the current. When the temperature falls a few degrees the heat is turned on again. Since this action is automatic workmen need not watch the

The Wallace bench glue pot

temperature and an increase in production is the direct result. The temperature gauge dial always shows the heat attained and together with the jewel, set in the base casting, acts as a visible check on the heat maintained.

The glue pot operates from any electric lighting circuit and is put in operation by merely turning the switch. The Wallace bench glue pot functions either as a water bath, hot air or dry heat pot and whichever way it is used it can never overheat though the current be left on over night.

There is a durable cast aluminum glue container supported by special retainer lugs which prevent floating when the pot is but partly filled. The escape of moisture is greatly minimized by this method of suspension. The base cover forms a dead air heat insulator chamber between the heating unit and the bench, and the air gap which surrounds the heating unit is further insulation between the heat unit and the base casting. The insulation and control of the current for fire protection have been approved by the Underwriters Laboratories. Part of the bail extends across the center of the pot as a brush wiper eliminating overflow and dripping.

This glue pot is adapted for heating any substance which requires a definite working temperature, such as heating or melting glue, wax, pitch, tar, sealing compound or resin and the following are the principal advantages claimed:

Wholly automatic in action and therefore requires no attention from workmen.

Glue is kept always and invariably at correct temperature for maximum strength and viscosity.

Eliminates losses through spoilage of work due to overcooked or underheated glue.

Can be used either as water bath or hot air or dry heat pot.

Can be used as glue cooker or as warming pot in connection with central glue cooker.

Heats quickly, thus saving time in getting work under way.

Cannot cause fire from being left on over night.

Maintains heat with minimum expenditure of electricity.

Does not boil, waste nor injure glue from over or under-cooking.

J. D. Wallace & Co. of Chicago make these glue pots in two, four and eight quart sizes and weights range from 20 to 40 lbs.

Machinery Exhibits at the Canadian National Exhibition

The Canadian National Exhibition is recognized throughout the length and breadth of the country as one of the best ways for seeing the latest and best in all lines of industrial achievement. This is quite as true of the woodwork industry as of any other and there is no doubt but that those of the wood-using industries who took a day off to visit this great industrial exposition, found many things of such a nature as to be helpful and useful in their every-day work. In the Machinery Hall especially, there were a number of exhibits that were worth any woodworker's while to visit, for they displayed some of the latest ideas in woodworking machinery and demonstrated some of the most up-to-date methods for working up wood in its various stages of manufacture. Among the woodworking machinery manufacturers who had space at the Exhibition were the following:—

Preston Woodworking Machinery Co., Preston, Ont.—The exhibit of this firm comprised several of their latest machines, the display being exclusively ball bearing and motor driven. The equipment comprised:—

Ball bearing, motor-driven, beltless swing saw.

Pony planer, fitted with four knives, round cylinder, sectional rolls and chipbreaker, ball bearings and

Stockbridge electric knife grinder for grinding knives on the machine.

No. 125 variety saw table with tilting table, ball bearing mandrel and individual drive.

Two-spindle ball bearing shaper with stand at rear carrying motor in place of countershaft. This machine has a detachable spindle top to avoid disturbing set-up when it is wanted temporarily for a new job.

Light hollow chisel Mortiser.

No. 132 36-inch band saw finisher in a grey enamel.

* * *

P. B. Yates Machine Co., Hamilton—This firm's exhibit included an A 1 planer and matcher; G 2 ball bearing edging and ripping saw and a No. 8 A.B. box nailing machine, which is the latest model of this class of machine. It nails a complete box in three strokes.

* * *

A. R. Williams Machinery Co., Toronto—This firm made quite an extensive showing of woodworking machinery, among which were the following:—

McKenzie rip, cross-cut and mitre saw table with boring attachment.

Williams tilting saw table with raising and lowering mandrel.

American Universal floor surfacer.

Oliver portable ball bearing bench planer and jointer with 60-cycle motor mounted on the cylinder.

Oliver bench jointer with round cylinder, driven by 25-cycle motor through a belt, the motor being on a pivoted mounting so as to keep the belt tight.

Beach No. 8 rip and cut-off saw with jointer and boring attachment. This is a machine of special interest to contractors.

Crescent No. 107 Universal Woodworker which combines a 26-inch jointer with round cylinder, band saw, rip and cross cut saw table, reversible shaper and boring machine. In addition, special attachments such as a hollow chisel mortiser and sander may be added. This machine is made in a variety of sizes.

20-inch Moak jointer.

Moak band saw with aluminum top wheel.

* * *

Cowan & Co., Galt,—The machines exhibited by this firm included some of their latest productions—power feed rip saws, hollow chisel mortiser, belt sander, automatic knife grinder for planer knives, and chain saw mortiser.

* * *

Elliot Woodworking Machinery Co., Limited, Belleville—In addition to the regular Elliot No. 5 Woodworker, this firm showed a 16-inch planer and a new saw table with jointer attached operating from a lighting socket. A new development also displayed was their regular floor sander with a vacuum attachment for the removal of dust.

* * *

Bond Engineering Works, Toronto—This exhibit comprised transmission specialties such as bearings, pulleys, cones, shafts, hangers, truck casters, etc.

Dodge Mfg. Co., Limited, Toronto,—This exhibit included power transmission equipment manufactured by this well-known firm, including their famous wood split pulleys.

D. K. McLaren, Limited, Toronto—This firm displayed their lines of belting, fasteners, lacings, D.K. wood split pulleys and Philips pressed steel split pulleys.

Dominion Belting Co., Hamilton—Leather belting.

Beardmore Belting Co., Toronto—Leather belting.

A New Glue Treatise by Bogue

Veneer workers and other glue users in the woodworking industry have long felt the need of reliable information upon the manufacture, testing, analysis and general application of gelatin and glue. The books on this subject are comparatively few and very often inadequate in the information they impart. Indeed, there have been developments and improvements in the art of glue manufacture and glue handling that find no place in the standard texts on the subject but have been dealt with only through the medium of technical and trade periodicals. Glue users will therefore welcome the appearance of one of the McGraw-Hill Book Company's new publication entitled "The Chemistry and Technology of Gelatin and Glue," which has been written by R. H. Bogue, Ph. D., industrial fellow of the Mellon Institute of Industrial Research of the University of Pittsburg and research chemist for Armour & Co. of Chicago.

While the statement is made by the author that efforts have been directed towards studying the subject from the point of view of the chemist rather than that of the plant technologist, there is a great deal of information that has very practical application and will be of value to the practical woodworker and glue user. A sample of some of the less theoretical aspects is provided in the series of articles that have been appearing of late in the Veneers and Panels section of the "Canadian Woodworker." These articles which have been written by Mr. Bogue for this journal, are based on material that appears in his new book.

To indicate to those interested in the scope of this work, the following is the list of contents:—Part 1. Theoretical Aspects. 1.—The Constitution of the Proteins. 2.—The Chemistry of Gelatin and Its Congeners. 3.—The Physico-Chemical Properties and Structure of Gelatin. 4.—Gelatin as a Lyophilic Colloid. 5.—Gelatin as an Amphoteric Colloid. Part 2. —Technological Aspects. 6.—The manufacture of Glue and Gelatin, by Ralph C. Shuey. 7.—Water Resistant Glues and Glues of Marine Origin. 8.—Tht Testing of Glue and Gelatin. 9.—The Chemical Analysis, Detection, and Estimation of the Gelatin and Glue. 10.—The Evolution of Glue and Gelatin. 11.—The Uses and Applications of Glue. 12.—The Uses and Application of Gelatin.

Sturtevant's New Catalog

The B. F. Sturtevant Co. of Hyde Park, Boston, Mass. has just issued a new 72 page "Engineering Bulletin on Pneumatic Collecting & Conveying." It contains 33 pages of pictures and diagrams, 17 pages of useful tables—how to find the size of fans, the suction, volume, r.p.m. and horsepower for any system, cubic feet of air handled per minute, size of pipe and ducts used, and various other valuable tables. Data is also given on dust collecting from grinding and polishing machines, tumbling barrels, sand blast machines, coal breakers, shoe machinery and the removal of fumes, gases, etc. In addition, there are parts on the conveying of pulverized coal, fibrous materials, coffee, ashes, wool, wood chips, etc.

Upholstering and Trimming

Down Upholstering With a Tufted Back

The Operations Involved in Covering a Roomy Chair With a Tufted Down Top Stuffing Over Springs

The chair frame illustrated in Fig. 137 introduces a new element in the handling of down upholstering, because this type of chair is best treated with a tufted back. The untufted back was dealt with in the last issue. The frame of the chair described in the present article is of generous dimensions and permits of the employment of springs in the back, thus creating a more luxurious type of upholstering than is possible without springs. The same chair, however, can be made with pad back.

In Fig. 138 we show the seat of the chair upholstered in the muslin, the front edge having been built up with a nosing as described in connection with previous illustrations, and the seat kept flat as a foundation for the down cushion. If springs are to be employed in the back as shown in Fig. 139, the canvas to support the springs is tacked on the outside back of the frame. On the arms, where no springs are used the canvas is on the inside of the arms as shown in this illustration.

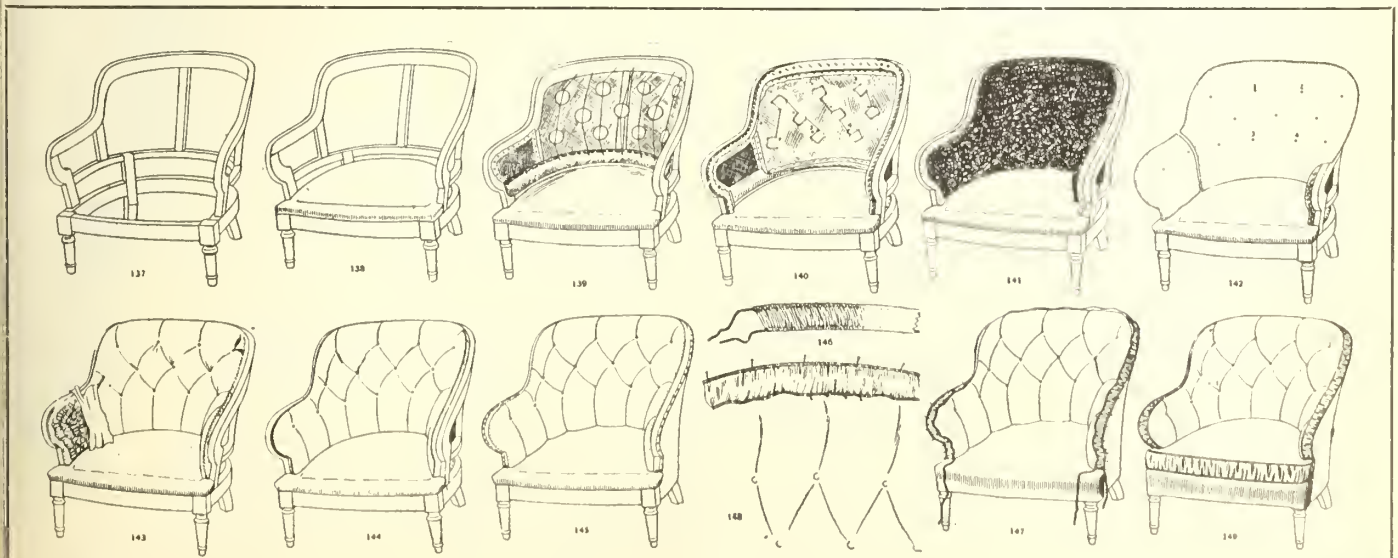
The pillow springs, employed in the back, are lightly tied down to keep them in place by twines which reach from the bottom to the top, but are not cross-tied, as cross-tying would interfere with the free play of the springs.

A stuffed roll forms a base for the upholstering and is built up around the bottom of the back as shown in the last mentioned figure. To this roll the canvass which covers the springs is sewn, as shown in Fig. 140. The canvas is also knotted to the springs, but is kept quite loose so as to prevent strain when the springs are depressed.

When the chair has reached this stage canvas for a nosing is back- tacked all around the edge of the frame, beginning at the lower extremity of one arm, circling around the back and coming down to the lower extremity of the other arm. This nosing is stuffed up as already explained in connection with other chairs. and lightly stitched so as to make a soft roll, square with the edge of the frame. The canvas at this stage is marked for buttons, as shown by the dots in Fig. 140, and tying twines are threaded through these dots, both ends being left free for subsequent use as shown in Fig. 141.

When the chair has reached the stage shown in Fig. 140 it is in condition to measure for the down pad which forms the top layer of filling. The down-proof ticking for the pad is cut the shape of the back, but an allowance of about three inches over all each way is provided for fullness. Note is made of the button marks on the canvas shown in Fig. 140 and similar marks are made on the pad covering, allowing an extra three-quarters of an inch between the marks for fullness. Thus, if the distance between marks 1 and 2 in Fig. 140 measured nine inches, the distance between the corresponding marks on the pad should measure nine and three-quarters inches and the distance between 1 and 3 in Fig. 140 would be increased about three-quarters of an inch on the down pad.

The entire back is next overlaid with hair between the twines, the twines being held upright during the manipulation of the hair so as to keep them free. The entire hair filling is applied by successive layers as shown in Fig. 141, keeping the edges neat and the nosing free so that the down-filled pad can be sewn to the nosing without interference.



Cycle of operations in the upholstering of a tufted back

When the chair has reached the stage shown in Fig. 141, the down pad which is made knife-edged (i.e., with no border), having previously been sewn and comfortably filled with about one inch of down, is pinned into place, as shown in Fig. 142, for the final fitting of the arms, which are made separate and sewn together after filling and fitting.

The strings which projected through the hair in Fig. 141 are now brought into play and the down-filled pad being treated as if it were the covering muslin, is tufted into place, the fullness being arranged into pleats and the edges sewn all around the nosing, as shown in Figs. 143 and 144. Where the tufting is tied in, it is advisable to use a small piece of cotton wadding beneath the twines, making the knot from underneath the pad rather than on top.

The next operation is the tufting on of the cover as indicated in Fig. 145. Instead of using buttons on light-weight silks, it is a practice in the fine shops now to use a French knot, made up of a small piece of the covering, sewn in rosette shape and tied through after the manner of an ordinary button. The outside lining is also put on when the chair reaches the stage herein indicated and the final finishing of this particular chair consists of the application of a ruffled band which covers the top edge of the back and arms. This band is cut the proper width to cover the raw edge of the covering which is sewn to the nosing around the outlines of the arms and back and an allowance of 100 per cent. for shirring purposes is made over the quantity required by the chair's outlines.

The edges of the band are turned over a soft cable cord and sewn close to the cord but not so tightly as to prevent the fabric slipping freely along the cord. (See Fig. 146.)

Having determined the measurement from X on the right hand side of the chair shown in Fig. 145 around the back to X on the left hand side of the chair, the band is shirred into this measurement, keeping the fullness evenly distributed. It is then pinned around the outside edge as shown in Fig. 147 and then on the inside edge. The band is pinned to the nosing (covering the edges of the cover in a straight line) manipulating the fullness as the work proceeds so as to keep the pleats radiating always in a straight line from the centre of the chair. The method of handling this fullness is indicated in Fig. 184.

After the front edge of the seat has been covered with a band of the same material as the chair covering, the down cushion made and edged with a ruffle similar to the back ruffle, the chair will have the appearance shown in Fig. 149.

Upholstery Sample Abuse

Some old philosopher has said that we eventually pay for what we get for nothing, and such is the case in the retail furniture trade in the matter of samples of upholstery covers.

It has been the practice in years past for manufacturers of upholstered furniture to furnish small cover samples without charge. Gradually the retail trade began to request larger samples, and still larger, until recently 24 inch square samples have become the rule rather than the exception. As the demand for the larger sizes increased gradually, manufacturers were slow to appreciate exactly what these samples were costing them. In fact, it is only a matter of months since the real expense involved was figured at all, and the result was astounding.

One manufacturer, whose largest business is in medium grade goods, kept an exact record on thirty-four sets of sample books, and he was dumfounded to discover that these thirty-four sets had actually cost him almost eleven hundred dollars. The bill for the cloth alone was eight hundred dollars—then there was the additional cost of the covers, the printing, binding, etc.

Although the industry was slow to recognize the leak this practice produced, it has finally reached the stage of national comment, and practically all of the large houses are now making a charge for large samples. They will furnish small samples to their customers without charge, but they are asking their dealer friends to pay for the big ones if they want them.

This change in policy was born of necessity. With a sample cost of one hundred dollars for every thousand dollars worth of goods shipped, it is evident that this practice would lead to disaster if it were allowed to continue and to grow. The cost of the samples was not figured into the cost of the goods, hence, in most instances, these costs formed a "leak" which did not develop until the day for accounting arrived.

Retailers, being good business men, appreciate the necessity of eliminating all waste in industry, and the vast majority of them quick to see the manufacturer's viewpoint. Now, instead of carrying a number of large sample books secured from various manufacturers, they find that one book, together with the smaller sample books of a number of makers, is usually sufficient for their needs. And they value the samples they have paid for far more than they valued the old ones which were given them without charge.

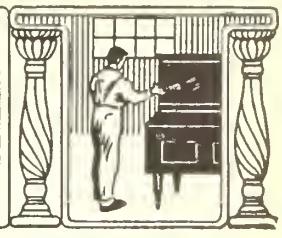
THE FINISHING ROOM



New Developments in Stains

The Manufacturers of Wood Finishes are Constantly Working Out New Ideas to Give Good Effects at a Reasonable Cost

By C. J. Lavallee*

In the past few years there have been many improvements in the manufacture of wood finishing materials, particularly stains. In this process of development there have been many obstacles, of course. In the first place the manufacturer of wood finishing materials has had to contend with so variable an element as wood, and wood as used to-day would have been regarded by the manufacturer of twenty-five years ago as unfit for use. Every piece differs in texture and other characteristics. Hence, the stains must be made not only to meet new conditions, but to conform to the tastes of the different furniture manufacturers.

Stains Developed Primarily for Furniture

The stain business has really been built up around the furniture industry, and all the study and research given to the manufacture of stains was made necessary by the demands of the ever changing furniture designs and periods. The period furniture problem was brought about by the makers of the highest grades of furniture sending their men all over the world to visit the ancient castles, cathedrals, etc., to study at first hand the still remaining furniture of the different historic periods and copy them for their trade. They would copy both the design and color and come back and put them out, named after the period in which each had been in vogue. These manufacturers made their own stains as a rule.

As soon as they would get them on the market, the manufacturers of medium-priced furniture would take them up and endeavor to place these heretofore exclusive creations within the reach of their trade. They would come to us with the problem of matching the period finishes at a fraction of the cost of the higher priced goods. In this work we were really successful, and thus played our humble part in enabling the people as a whole to possess furniture representing the highest art at moderate prices.

The Kinds of Stains

Stains are divided into four general classes, water or acid, chemical, spirit and oil. The water or acid stain is fine, as you know, and on some woods will produce better results than anything else. But it has one serious drawback—it raises the grain and necessitates a great deal of sanding, which is expensive. A chemical stain is practically the same thing as a water stain, except that it does not contain aniline dyes.

The spirit stain is made from an aniline dye soluble in alcohol. It is very brilliant and beautiful, and easily handled, but unfortunately it is very fugitive and fades quickly when exposed to the light.

Then there is the oil group. The oil stain is the most practical so far as stains made on an aniline base are concerned, and is used extensively with good results on certain classes of work. But if the surface over which it is used is to be varnished, it has its very serious drawbacks in that it does not allow the varnish to dry properly. This is well understood by most finishers who have used them and there is naturally a very strong prejudice against oil stain for that reason.

We ourselves made very large quantities of oil stains, knowing their shortcomings, but there was nothing on the market that was any better. Later we got out improved stains, which embodied the good qualities of the different stains just enumerated with most of the faults removed.

But I want to consider a new stain, which was first made for the furniture manufacturing trade. It is a pigment stain and will be better understood by the painter, who has been making such stains for years. But while this is a pigment stain, it contains some materials that the painter is not familiar with and could not use if he were, because of the manner of putting them together. We have named it our "uniforming" stain.

You will be interested at this time, because you are, I am sure, asked to produce walnut or mahogany effects on gum wood. This uniforming stain made in both walnut and mahogany enables you to produce a correct effect in either of these shades on any kinds of wood, whether good red gum or the worst sap gum, or both together. Very good results can be obtained on either birch or pine. You can well realize that, because of the pigment it contains.

*President of the Marietta Paint and Color Co., before the Ohio Association of Master Painters and Decorators.

Two Finishing Firms Combine

There has just been announced the consolidation of the Grand Rapids Wood Finishing Company and the Walter K. Schmidt Company, of Grand Rapids, Mich. The Walter K. Schmidt Company has always held a unique position in the industrial field, specializing mainly on dyes, dyestuffs, and chemicals and in their service department rendering a unique service in matching, creating and making of stain powders. Their laboratory has devised many new methods for the production of new finishes on wood.

In January 1893 was founded the Grand Rapids Paint and Color Company which was reorganized in 1903 becoming the Grand Rapids Wood Finishing Company, devoting its attention to the furniture and general wood working industries, specializing in stains and fillers.

The personnel of the new company will henceforth comprise men well versed in the various phases of the company's activities. They are represented on the road by eight salesmen, six of them experienced finishers and two specialty men.

Night Finishing a Waste of Time and Space

Disadvantages of Over-Night Drying—Production Can be Speeded up by Drying the Article as Soon as Coated—Comparison of the Two Methods

The art of finishing today presents enough difficulties of its own, without our inviting additional trouble my sticking to outgrown ideas. The drying operation, for example, has become an exact process, both in time required and results obtained, yet many wood-workers are allowing out of date drying methods to slow up the whole factory.

Delays in the finishing process are due to two causes: first, the old idea that work must be coated during the day and dried over night; and second, old

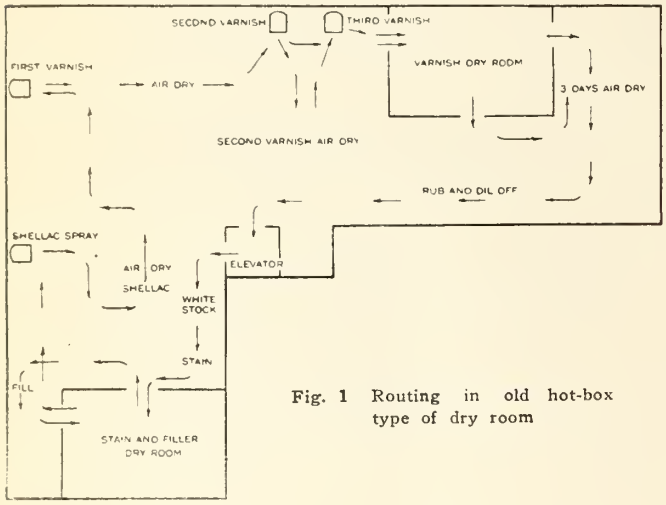


Fig. 1 Routing in old hot-box type of dry room

methods of routing the work, which involve much time loss through back-tracking. Both causes are easily removed by putting the drying operation on a modern schedule.

Disadvantages of Night Drying

In the last few years important changes have been made in the art of varnish manufacture, due both to the scarcity of certain ingredients and to the increasing demand for quick-drying coatings. New methods of applying the varnish coatings by spraying, flowing or dipping have resulted in fewer but heavier coats. Costs have risen in the finishing department, as in all other branches of wood-working. All these causes have made it necessary to install equipment capable of decreasing the finishing time, and so increasing the production for a given period.

While such equipment has been installed pretty generally, it has not been utilized to its full capacity except in the automobile industry. Wood-working plants, particularly those manufacturing furniture, pianos, phonograph cabinets, and similar articles, are actually getting only half-time production out of their dry rooms.

In progressive automobile plants the part is put into the dry room as soon as it is coated and dipped. In most wood-working plants the article is coated rapidly and efficiently, then allowed to stand until evening in the finishing room, or an open dry room, and dried over night. This delay causes work to pile up in various parts of the finishing room. It also allows the carefully applied finish to be damaged by dust, dirt, soot, insects and other foreign matter.

In addition, the old method of over-night drying usually produces incorrect drying. Most grades of varnishes are now manufactured for use in a dry room. If exposed to from five to seven hours of variable atmospheric drying, the coating has obtained a decided surface-set. Then when it is exposed for from eight to twelve hours to the more rapid drying atmosphere of the dry room, the surface becomes still further case-hardened. As a result, the oxidation of the drying oils and gums takes place at a relatively slower rate.

When once a siccative coating has obtained a decided surface-set, it cannot be correctly dried in a dry room, unless a sufficiently high relative humidity is carried to soften up the surface. Such an atmospheric condition will be very injurious to the other coated surfaces placed in the dry room the latter part of the afternoon.

This explains why the finishing department foreman is frequently puzzled, as he thoughtfully fingers his coated pieces after an over-night drying. Often he finds that the piece which was coated the last thing in the afternoon is more satisfactorily dried than its neighbor, which he knows was coated early in the forenoon.

Day and Night Drying Methods

The disadvantages of night drying can be easily eliminated by drying the article as soon as it is coated. This will make it possible to operate the drying

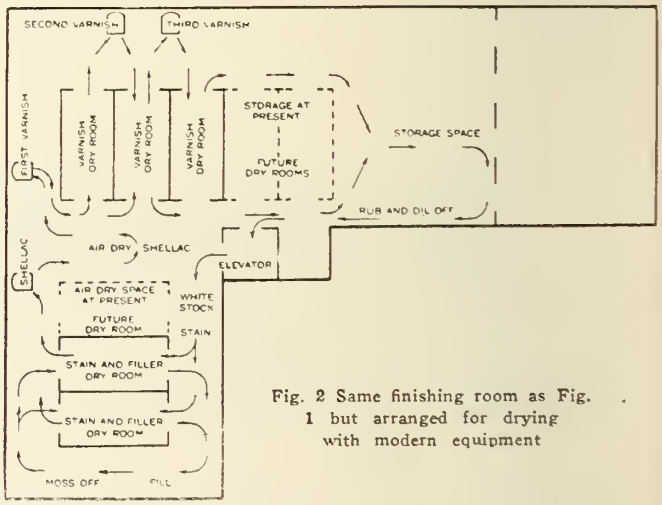

Fig. 2 Same finishing room as Fig. 1 but arranged for drying with modern equipment

room with two shifts, and so speed up production.

To illustrate accepted methods, we present a series of diagrams showing typical arrangements of dry rooms now being installed by progressive manufacturers. The accompanying drying schedules cover the various classes of finish used in the wood-working industry.

Diagram No. 1 shows the arrangement of dry rooms and routing of work in a typical furniture finishing room using the old hot-box type of dry room on an over-night drying schedule. Diagram No. 2

shows the same finishing room with the arrangement of dry rooms and routing of work when using modern drying equipment. The two drying schedules follow:

Old Schedule

Type of finish—medium and high-grade mixed suites.

Stain applied in daytime; in dry room over night.

Filler applied in daytime; in dry room over night.

Shellac or shellac substitute applied in daytime; air-dried over night.

First varnish coat applied in daytime; allowed twenty-four hours to air-dry.

Second varnish coat applied in daytime; in dry room over night.

Third varnish coat applied in daytime; dried over night.

Storage time between third coat and rubbing, three to four days.

Rub and oil off, one day.

Total time by old schedule, twelve to thirteen days.

New Schedule

Type of finish—medium and high-grade mixed suites.

Work stained in forenoon, put in dry room for four hours at 120-degs. temperature, 38 per cent relative humidity.

Work stained in afternoon; in dry room before 5 p.m., and dried for six hours, until 11 p.m., at 120-degs. temperature, 38 per cent relative humidity.

Work to be filled in forenoon, removed from dry room in morning; filled and mossed-off and dried for four hours at 120-degs. temperature, 38 per cent relative humidity; removed from dry room, sprayed with shellac or shellac substitute, air-dried over night.

Work to be filled in afternoon, removed from dry room, filled and mossed-off and in dry room by 5 p.m.; dried for six hours until 11 p.m. at 120-degs. temperature and 38 per cent relative humidity.

Work to be shellaced in forenoon, removed from dry room; sprayed, air-dried, sanded and first varnish-coated by 5 p.m.; dried for six hours until 11 p.m. at 116-degs. temperature, 42 per cent relative humidity.

Work to be shellaced in afternoon, removed from dry room, sprayed and air-dried over night.

Work to be first varnish-coated in forenoon, taken from space where it was air-dried over night, sanded, sprayed and in dry room for four and one half hours at 116-degs. temperature, 42 per cent relative humidity; sanded, second varnish-coated by 5 p.m. and in dry room for six hours until 11 p.m. at 116-degs. temperature, 42 per cent relative humidity.

Work to be first varnish-coated in afternoon, sprayed and in dry room by 5 p.m. and dried for six hours until 11 p.m. at 116-degs. temperature, 42 per cent relative humidity.

Work to be second varnish-coated in the forenoon, removed from the dry room, sanded, sprayed, dried for four and one-half hours at 116-degs. temperature, 42 per cent relative humidity; sanded, third varnish-coated by 5 p.m. and in dry room six hours, until 11 p.m., at 116-degs. temperature, 42 per cent relative humidity.

Work to be second varnish-coated in the afternoon, sprayed and in dry room before 5 p.m. and dried for six hours, until 11 p.m., at 116-degs. temperature, 42 per cent relative humidity.

Note: Work which is to receive only two coats is removed from the dry room to the storage space at the end of the drying period or in the morning.

Work to be third-coated in the forenoon, sprayed and put in the dry room up to 11:30 a.m. and dried for five hours, until 4:30 p.m., at 116-degs. temperature on the dry bulb, 42 per cent relative humidity; removed from the dry room and placed in the storage space, where it stands for approximately sixty hours before rubbing.

Work to be third varnish-coated in the afternoon, sprayed, put in the dry room up till 5 p.m. and dried for six hours, till 11 p.m., at 116-degs. temperature, 42 per cent relative humidity; removed from the dry room in the morning to storage space, where it stands forty-eight hours before rubbing.

Total time by new schedule, six to eight days.

Note: By the addition of one or more unit dry rooms, six hours more could possibly be saved between the application of the third coat and the rubbing period, with a proportionate increase in production.

A comparison of the old and new methods gives the following results:

	Old Method	New Method	Saving by New Method
Average time through finishing room, with allowance for Sundays and Saturday afternoons	14-15 days	6-8 days	7-9 days
Total floor space finishing dept.	16,200 sq. ft.	13,400 sq. ft.	2,800 sq. ft.
Total floor space, dryrooms	3,072 sq. ft.	2,560 sq. ft.	512 sq. ft.
Productive dry-room area	3,072 sq. ft.	5,120 sq. ft.	2,560 sq. ft.

In this case the saving of time in finishing averages 50 per cent. The actual saving of floor space in the finishing department is 17 1/3 per cent and in dry room space 16 2/3 per cent. Since, however, the new productive dry room area is really double by day and night drying, it might be said that the new method is saving the entire space occupied by the old method.

The release of stock in the finishing process approximates 40 per cent. The number of rejects has been decreased over 75 per cent and the dependability and uniformity of the drying has resulted in the prompt delivery of rush orders. Since the estimated cost of the old dry rooms is $5,200, as against $6,000 for the new, all these advantages are secured at an increase of only 15 1/3 per cent in the investment.

What the modern dry room can accomplish in factories having a large production of articles of practically the same size and shape, such as filing cabinets, phonograph cabinets, sectional bookcases, etc., is shown, the plant being equipped with seven drying rooms. In this instance the idea is to push through the finishing department the greatest possible volume of work in the least possible space and eliminate backtracking. The drying schedule follows:

Dryroom No. 1.

Load 7:30 a.m. to 9:30 a.m. ..... dry 9:30 a.m. to 1:30 p.m.
Load 1:30 p.m. to 3:30 p.m. ..... dry 3:30 p.m. to 9:30 p.m.

Dryroom No. 2.

Load 9:30 a.m. to 11:30 a.m. ..... dry 11:30 a.m. to 3:30 p.m.
Load 3:30 p.m. to 5.00 p.m. ..... dry 5:00 p.m. to 9:30 p.m.

Dryroom No. 3.

Load 7:30 a.m. to 9:30 a.m. ..... dry 9:30 a.m. to 1:30 p.m.
Load 1:30 p.m. to 3:30 p.m. ..... dry 3:30 p.m. to 9:30 p.m.

Dryroom No. 4.

Load 7:30 a.m. to 9:30 a.m. ..... dry 9:30 a.m. to 1:30 p.m.
Load 1:30 p.m. to 3:30 p.m. ..... dry 3:30 p.m. to 9:30 p.m.

Dryroom No. 5.

Load 9:30 a.m. to 11:00 a.m. ..... dry 11:00 a.m. to 4:30 p.m.

Load 4:00 p.m. to 5.00 p.m. ..... dry 5:00 p.m. to 9:30 p.m.
Dryroom No. 6.
Load 7:30 a.m. to 9:30 a.m. ..... dry 9:30 a.m. to 1:30 p.m.
Load 1:30 p.m. to 3:30 p.m. ..... dry 3:30 p.m. to 9:30 p.m.
Dryroom No. 7.
Load 9:30 a.m. to 11:00 a.m. ..... dry 11:00 a.m. to 4:30 p.m.
Load 4:00 p.m. to 5.00 p.m. ..... dry 5:00 p.m. to 9:30 p.m.

The average schedule for this installation is one day each for stain and filler, first varnish, second varnish and rub and oil off, making the average finishing time four to five days, allowing for Sundays and Saturday afternoons.

The total floor space in the finishing department is 17,600-sq. ft. and the dry room is 5,600-sq. ft., giving a productive dry room area of 11,200-sq. ft. The increase in the output is over 60 per cent and the decrease of material in process of finishing is from 30 to 35 per cent.—By C. H. Currier in Veneers, Indianapolis.

If you have a large number of screws to put into any class of wood, remember a machine will put them in five times as fast as a man.

Speeding up old machinery increases the risks of breakages and stoppages. Averaging these up, it will be found that what is gained one way is lost in another.

It's a whole lot easier for the small store in the small town or the so-called neighborhood store in the city to put a personal touch with each transaction.

Most folks do not think so, but there is an art in piling a stack of timber so it will be weather-tight, and dry without any undue warping.

Haley Bros. and Company Limited, woodworking manufacturers of St. John, N. B., have been operating without a pause at their big Broad Street factory. This firm is one of the best known woodworking manufacturing firms in the maritime provinces. It has representatives on the road throughout the maritimes and also caters to the provinces of Ontario and Quebec and the west. W. K. Haley, manager of Haley and Sons, is interested in the business life of St. John, and is a member of the Board of Trade. He is also vitally interested in playgrounds and has been president of the St. John Playgrounds Association, this organization having under his leadership progressed considerably in the expansion of activities and installation of new playground apparatus. Mr. Haley is also an active member of the St. John Y.M.C.A.

Increasing the Speed and Decreasing the Cost

of Your Finishing Room Operation

How practical, how advantageous and how dependable DeVilbiss spray-painting equipment is, has been demonstrated in finishing rooms of every size and line.

Not merely in dozens of finishing rooms, but in thousands of them. Not only where a few different kinds of articles are handled, but where every kind, size and grade of wood or metal product is finished. Not alone where varnishes, enamels or lacquers are used, but where every kind of liquid finishing material is applied. The

DeVilbiss

Spray-painting System

offers a complete, adaptable and guaranteed service. The finishing operation is speeded up 4 or 5 times over hand-brushing. A perfect, uniform coating is applied on all jobs. Working conditions are made more healthful and safer. Operating and upkeep costs are reduced to the minimum.

With your consent, we'll gladly tell you whether and how the DeVilbiss System can be of service and profit to you.

BeVeCo VENEERS

"Brown Bird's-Eye Maple"

As Featured During the Summer Markets

EVERY maker of furniture is interested in the new color given to Bird's-Eye Maple. Here the craftsman's experience has been utilized to enhance the handicraft of nature.

Brown Bird's-Eye Maple is simply beautiful. In its new dress it opens up a multiplicity of uses for which it is especially adapted. It is the most striking veneer obtainable for two-tone effects, Bedroom Suites, decorative panels, novelty furniture, inlays and overlays—and any place in which a rich contrast in warm distinctive color is desired.

Brown Bird's-Eye Maple has become a standardized shade. Ask your wood-finishing house for a sample panel. The simplicity and economy of producing this color is proved. Your foreman can do it, when he sees a panel.

We will be pleased to have a finished panel sent you from your finishing house. This will show you exactly how beautiful and how striking this new finish is. Just write for a sample panel, it places you under no obligations. We'll gladly tell you more about.

Best Way to Have Dry Veneers is to Keep Them Dry

Costly and Wasteful to Redry the Stock After Allowing it to Absorb Moisture in Storage—Why Not Control Heat, Humidity and Circulation in the Storage Room?

By S. H. Johnstone

"The best way to ensure having dry veneers is to keep them dry" recently remarked an old woodworker. He said he realized the importance of having the stock dry at the time of laying, but did not see the sense of permitting it to take up all the moisture it could absorb when in storage, and then redrying it just before the gluing operation. There is a lot of good practical commonsense in his ideas. How many times have you noticed veneer in storage under conditions that were far from what they should have been. For my own part I have seen expensive stock stored in an old leaky barn in the loft of some lean-to or annex or in some little used part of a damp basement. Under such conditions the material is bound to take up a lot of moisture, regardless of how dry it was when it was received, and if such moisture is not removed before the gluing operation, checks and open joints are likely to result.

Keeping such material in a special storage room or in some little-used part of the plant is better, for it is not so likely to be exposed to leaks and other forms of extreme dampness, but even under such conditions it is subjected to all the changes and variations which take place in the surrounding atmosphere. The result is that the moisture content of the material is not known, and resort must be made to redrying to secure uniform evenly dried stock.

To anyone who has not paid much attention to the way the moisture content of wood varies with every change in atmosphere conditions, the suggestion that storing veneers in the plant is not satisfactory, may sound like splitting hairs, but at the same time the suggestion is not without its significance. Take a few thin cross sections of wood and hang them up in various places throughout the plant and then weigh them every day and see how the weight will vary. As the humidity of the surrounding air increases, the pieces get heavier whereas if the surrounding air loses its humidity the test pieces respond and test lighter. Here we are not concerned so much with how much the piece will vary from one extreme to the other but the fact that it does vary precludes the possibility of storing veneer in the open shop and then using it with any degree of certainty that the moisture content is as it should be.

In many plants more attention is given to the storing of the thin stock. Special warm, dry storage rooms have been provided in which the flitches and rotary-cut stock are piled in neat, regular piles. Some even go a step further and hang a thermometer in the veneer storage and try and hold the temperature at some predetermined point.

All this is fine, but even so it does not ensure perfectly dry veneer. In the dry kiln, heat, humidity and circulation are controlled so that conditions in the kiln may be so regulated that the lumber is dried to the desired point. Why not go a step further then and turn the veneer store-room into a dry kiln in which the heat, humidity and circulation are under rigid control, permitting conditions to be held constant so as to give any E. M. C. desired. While an E. M. C. (equilibrium moisture content) of four or five per cent would be about correct, the conditions which would be maintained should be very mild, say a temperature of from 100 to 120 with humidity to suit.

If this is followed out what happens. Regardless of the condition of the stock when placed in storage it will gradually come into equilibrium with the controlled surrounding atmosphere, which means about 5% moisture content. That moisture content will remain constant as long as the surrounding atmospheric conditions are not allowed to change. The result is that the stock can be taken from the storage and worked up with the full assurance that it is in proper shape.

Following out this suggestion would not entail a heavy expenditure and would eliminate the necessity for redrying, either in special kilns or with special equipment. Nor is this the only economy which would result, for the drying loss attendant in redrying would also be saved. This should have an appreciable effect on the cost of all the products into which veneer enters and at the same time facilitate the movement of stock through the veneer department, for the delay and confusion, attendant upon redrying would have been eliminated. After all, the best way to ensure dry veneers is to keep them dry.

"Modern Glues and Glue Handling"

The Periodical Publishing Co., Grand Rapids, Mich., has just turned out a new treatise entitled "Modern Glues and Glue Handling," by Clyde H. Teesdale, who was formerly in charge of the section of wood preservation of the Forest Products Laboratory, Madison, Wis..

This book is based largely on the results that were obtained from the investigations which were carried out in the laboratory in connection with developing specifications and methods of test for glues used in aeroplane work. The result is that the contents of the book are eminently authoritative and practical. Glue users will find that they can considerably augment their present knowledge of glue handling by a thorough study of this treatise, the contents of which are divided under the following chapter heads: — General Discussion; Miscellan-

eous Glues; Uses of Glue Testing (Preliminary); Glue Testing; Viscosity; Jelly Strength. Strength of the Glued Joint; Plywood Strength Test; Specifications; Results of Tests on Miscellaneous Glues; Grading the Glue Sample; Some Interesting Strength Data on Glues; Use and Application of the Glye Hydrometer.

An appendix outlines the methods of testing animal glue at the Forest Products Laboratory.

Conditions Affecting the Adhesive Strength of Glue

The Influence of Joint Trueness and Gluing Procedure—How Pressure Influences Strength—Curing Conditions

By R. S. Bogue, Ph.D*

(Continued from last issue)

In the August issue the first of two articles on conditions affecting the adhesive strength of glue dealt with four of the factors involved, viz., (1) The concentration of the glue solution; (2) the time occupied and the temperature employed in heating the glue; (3) the temperature of the glue when applied; and (4) the species, density, porosity, and moisture content of the wood used. In this article the effect of nine other conditions is explained, completing the discussion on this important topic which is of interest to every glue user.

(5) The Trueness of the Joint.—The strength of a glued joint must be proportional to the area of the effective surface of the joint. If, in a joint of 4 square inches, only 3 square inches are in intimate contact, it must follow that the strength obtained will be much less than if the whole joint is in contact. Very little strength is developed by using glue as a mortar. The joined surfaces must be perfectly true to obtain the maximum strength. Sand paper should not be used to remove the last imperfections in the surface, for the powdered wood which is scraped off fills up the pores of the wood, and retards the penetration of the glue. A good plane should be the final tool employed. Under no circumstances, however, should tests be made upon joints which are not perfectly true.

(5) The Amount and Method of Application of the Glue in the Joint.—One often hears warnings against the "starving" of joints by using too little glue upon them. Of course, it is possible to use too little glue, and obtain a weak joint, but if the material is applied with a brush, or even a roller that is properly supplied, the danger of applying too little glue is almost negligible. The tendency among the consumers of glue is rather to use far more than is needed and squeeze out the excess. The waste in this procedure is often very great.

But little is ever heard regarding the other possibility—that of "overfeeding" the joint. If a large amount of glue is applied, and the excess is not squeezed or rubbed out, the danger of "overfeeding" may be a very real one. As the glue dries out in the joint it contracts, forming a honeycomb appearing structure, and joints of exceeding weakness may result. Whenever a broken joint reveals this uneven, honeycomb appearance it is sufficient proof that either there was too much glue allowed to remain between the two pieces of wood, or that the joint was not true, resulting in the same effect. The common practice of rubbing the joint together after applying the glue is beneficial only in that it works out of the joint the excess of glue. It may be safely said that the dangers of "starving" a joint are mostly illusionary, but the danger of "overfeeding" it are always imminent. If the amount applied is adequate, it is virtually impossible to rub or squeeze out so much that the joint is weakened thereby.

(7) The Temperature of the Wood when Glue is Applied.—When a warm glue solution is applied to a cold piece of wood, the layer of glue immediately adjacent to the wood will be chilled to the setting point before it can properly penetrate the pores of the joint. This must result in a joint considerably weaker than the maximum obtainable. The wood should be warm, but not hot. Excessive heating will expel more water than is desirable, and tend to warp the wood, making a true joint difficult to obtain. For this same reason the temperature of the glue room should be as high as is consistent with the comfort of the workmen, and a brief warming of the wood prior to the joining will be sufficient.

(8) The Rapidity of Handling.—A condition is observable in some plants where, on account of ignorance or indifference of the results incurred, an unnecessary lapse of time is allowed between the application of the glue and the placing of the joint under pressure. In such cases the glue has chilled and set to a jelly before the pressure is applied. In order to understand the detrimental effect of such a practice it must be emphasized that the influence of pressure is only to squeeze out the excess of glue, and to minimize the inequalities in the perfection of the joint. By permitting the glue to jelly before applying the pressure is to rob the pressure of its usual effect. A jelly will not readily be squeezed out. The result is a joint which contains an excess of glue between the sections, and, as shown in a previous paragraph, this very materially weakens the joint. The pressure should always be applied as quickly as is consistent with good workmanship after the spreading of the glue.

(9) The Pressure Applied to the Joint, and its Uniformity of Distribution.—So far as the author is aware, the only carefully conducted tests that have been reported upon the relation of the joining pressure to the strength of the joint are those described by Gill in 1915, and the investigations of the writer in 1920. Gill employed a joining pressure varying between 10 and 100 pounds to the square inch, and reported that "a pressure of 30 pounds to the square inch gave a joint about 15 per cent stronger than either the 10 or 100 pound pressure." The data obtained for the tests at the different pressures are not given, but the variation between the maximum and minimum values obtained is very great—averaging in the neighborhood of 200 per cent. This being the case it seems difficult to regard the 15 per cent variation reported for different pressures as significant.

Experiments which have been conducted in the writer's laboratory have shown high pressures are not only harmless but decidedly beneficial from the the standpoint of the ultimate strength developed.

---

*Industrial Fellow of the Mellon Institute of Industrial Research and Research Chemist for Armour & Co., Chicago.

This article represents a part of the section of the "Glue as an Adhesive" in the writer's treatise on "The Chemistry and Technology of Gelatin and Glue," published by the McGraw Hill Company of New York.

(Continued from page 80)

Joining pressures varying from 10 to 1,400 pounds to the square inch were used. These pressures were obtained by placing the joints, very carefully prepared, between the parallel plates of an Olsen universal testing machine. A ball-bearing was used both above and below the steel plates to insure a perfectly uniform distribution of the pressure. Previous tests made by using clamps had shown the impossibility of obtaining either a constant or a uniformily distributed pressure by that means.

The data show the strength of the joint to rise rapidly with increasing joining pressure between 10 and 200 pounds to the square inch. Above the latter pressure the strength continued to increase slightly to 1,000 pounds, and thereafter remained constant to 1,400 pounds. This is illustrated by the curves in figure 1.

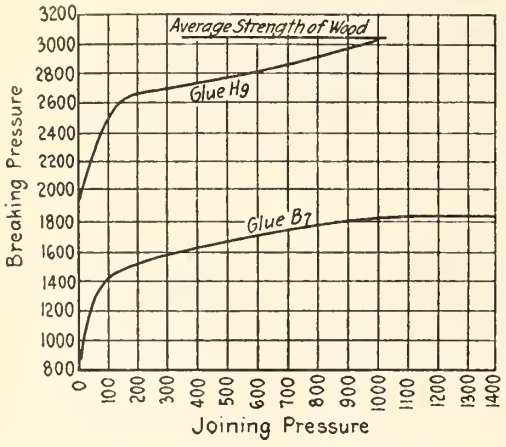

Fig. 1— The effect of joining pressure on strength

In the light of the frequent assertions made that "too much pressure must not be used in gluing surfaced wood, as the glue may be pressed out too completely from the joint, producing a so-called starved joint," a consideration of the meaning of these data may not be out of place. The writer has repeatedly emphasized that a glue is not a cement. Let us exaggerate the conditions for a moment in order to fix our point. Suppose that it is possible to make a joint of two pieces of wood, and that a large enough excess of glue is added to produce a layer of jelly an eighth of an inch between the two pieces. This jelly, we all know, is two thirds or more water. On setting, therefore, the water is evaporated off, leaving the one third or less of solid glue material. The evaporation of the water sets up strains and stresses in the material. The jelly contracts, draws away from the surface, and becomes contorted. Such stresses may even produce cracks in the dried glue, and a certain degree of porosity may be observed. Obviously a joint so made would show great weakness. This is an absurd case. No glue man would think of making such a joint. But assume that the jelly layer is reduced to a fiftieth, or a hundredth or an inch. Then we have conditions that are common. But the effects outlined above would still be present, and in exact proportion to the thickness of that layer. As the layer of glue between the wood pieces is made vanishingly small, the strength of the joint will approach its maximum value. The bond between the two pieces of wood should consist only of the vertical and interlaced threads of glue passing from the pores in one piece to the pores of the other.

If this is the case, and we seemed justified in making that conclusion, then it must follow that, provided the glue is properly applied, and in a condition such that a fair degree of penetration results, there can be no such an effect as a "starving" of a joint, and no such thing as too much pressure, as far as the glue is concerned. The advantageous results realized by high pressures can be explained only upon the assumption that such pressures are necessary to squeeze out the maximum amount of excess glue in the joint, and to minimize any slight inequalities in the perfection of the joint.

It should be stated that the crushing strength of the wood used sets a very definite limit to the pressure which may be applied with safety in any case. The porous types of wood will be injured by pressures which have no effect upon the denser varieties. And a thick piece of wood will stand without injury much higher pressures than could be used in thin-cut veneers.

(10). The Time under Pressure and Time of Curing.—If the pressure is removed from the joint before the glue has been given a sufficient time to harden, the two pieces will separate slightly, resulting in a weakened joint, and if the joint is broken before the glue has thoroughly dried out, the strength will be that of the partially solidified jelly, rather than of the completely cured glue. The writer finds that the pressure should be maintained for about 10 to 12 hours, and the curing for about seven days, in order to obtain the maximum strength.

(11). The Temperature and Humidity During Curing.—The rapidity and thoroughness of drying out depend in a large measure upon the temperature and humidity of the curing room. A low temperature and a high humidity make it almost impossible to obtain a perfectly cured joint. The glue, under these conditions, remains in the form of a partially dried jelly, but does not completely dry out. The opposite conditions of a warm temperature and low humidity are most favorable, both to the rapidity and the thoroughness of the curing.

Some glue consumers are in the habit of heating the joint, after it has been completed, to a rather high temperature for several hours. This practice has no advantages, as it keeps the glue in the liquid condition for a long period, and results in a much weakened product. Gill has shown that a heating of the glued blocks to 65 degrees for several hours diminished the strength very materially. This is fully corroborated by the writer's experience.

(12). The Method of breaking the Joint.—The results of the so-called strength test are usually reported in pounds per square inch, but is must be urged that the method by which the break is made is of the greatest importance. As will be shown in the following pages, the joints are made and broken in several ways. The joint may be end to end or side to side, and it may be broken by pulling apart, by shearing apart, or by applying the load at the joint, while the two ends are supported. The results obtainable vary widely. Very few results by different methods are rightly comparable, but the writer has found the observed "strength" per square inch to be about 500 to 600 per cent higher when blocks of 4 square inch area were sheared apart by pressure, than when strips of 1 square inch area were sheared apart by pulling. A standard procedure should be adopted and the method of the Forest Products Laboratory at Madison, Wisconsin,

Conditions Affecting the Adhesive Strength of Glue

(Continued from page 82)

appears to possess the greatest advantages of any that have been proposed.

(13). The Hydrogen-Ion Concentration of the Solution.—It has been shown that the viscosity, jelly consistency, swelling, and practically all properties of a gelatin vary according to the hydrogen ion concentration of the solution. A number of tests have also shown that the adhesive strength of a glue varies in a similar way, the maximum being attained at a hydrogen ion concentration in the neighborhood of PH=3.5 and 7.5, while beyond these limits the strength drops rapidly. A distinct diminution in strength is also found to follow the bringing of the solution to the isoelectric point—pH 4.7. Sherrick has observed the same tendency in the adhesive qualities of glues prepared for hectographic plates.

Creating a Profitable Market For Your Waste

A Variety of Novelties and Toys Can be Easily Manufactured From the Odds and Ends Around the Plant and Sold at a Large Profit— Little Extra Equipment is Necessary

By R. N.

In days gone by when lumber was plentiful and cheap, the question of waste gave very little trouble to the average woodworking plant. Under present-day methods of operation, however, when it has become essential that every foot of lumber used in the plant should be converted into marketable products, the situation is somewhat different.

There are millmen at the present time who will contend that it is a fallacy to try to convert the waste of the plant into useful and saleable articles. This may have been the situation in the past but the inventive genius of the woodworking machinery manufacturer, seeing the need of equipment for working up this waste, has provided machinery to convert at a profit the ordinary wood waste of any dimension into articles for which markets can be found at the present time if plain business methods are followed in this respect.

There are firms who turn out products made of wood, who will not allow their accumulation of odds, ends and offal to be used up. An effort is often made to dispose of this otherwise perfect wood by the management, but generally this results in failure due either to not coming into contact with the right parties or to prices offered which makes it more profitable to use the waste for fuel purposes.

If these firms would convert their offal and waste into marketable products themselves, they would often realize enough profit out of it to pay their entire payroll throughout the year. This, however, cannot be accomplished by trying to unload the waste on the other fellow to work up, and then continue merrily along butchering up more of it to keep him supplied. The only manner for realizing a profit out of the waste is to convert it right at the plant where the waste occurs, into merchantable products.

It is quite true your present equipment may not be suited to working up the small pieces of wood, but what of that? There are machines on the market that are made exactly for this purpose. If you invested one thousand dollars in new machinery to convert your waste into merchantable products and your sales from this source would total fifteen of twenty thousand dollars the first year, how long would it

Nature's Art

"I think that I shall never see
A poem lovely as a tree."
—By Joyce Kilmer,
a young American poet who gave his life in Flanders.

CONSIDER the sheer beauty of Willey's rare veneers. Tracery as delicate as frostwork on a window pane, designs as intricately graceful as a Moorish arabesque, can be found hidden in the heart of a tree.

Engraved by the slow-fingered years, each pattern unique as a finger-print of Father Time himself, these treasures of the woods have been gathered from far and near.

Willey's Veneer Plant has the largest existing collection of these natural art treasures from the world's forests. The inherent beauty of each specimen is revealed and enhanced in the highest degree by the work of our skilled artisans.

Willey's Veneers enrich the interiors of countless superb buildings, elegant apartments, and cosy homes. The polished and paneled background of civilization, from the Middle Ages until the present time, has been wrought from the heart of the tree.

Endless variety from which to choose the grain and texture best fitted for your special use, expert preparation and speedy delivery to supply your special need—these are features of Willey's service, which we will gladly place at your disposal.

be before this department would pay for itself? Furthermore there are hundreds of woodworkers idle to-day for want of work while on the other hand the fact has been disclosed that thousands of dollars' worth of wooden toys and novelty woodwork have been imported from foreign countries.

And why is this?—It's simply this. over there they are like the Chicago packers who lose nothing but the squeal; They lose nothing of the wood in its conversion except the whir of the saw or the hum of the planer.

To back up my contention in this regard, I will cite a few articles for which there is an almost steady demand the year round. Then if you take one of the large mail order house catalogues and refer to similar-styled articles and the prices they retail at, you will come to realize that all the profit is not always made from products that require a large volume of lumber in their production.

Take, for instance, Fig. No. 1 which represents a doll's bed made in a size 20 inches long, 10½ inches wide and 10 inches high. Its entire construction will scarcely require more than one square foot of 1-inch stock, yet the completed article sells for as high as $1.50 to $2.50. This is a product in which almost the smallest of waste can be worked up, and any kind of wood can be used. Fig. No. 2 shows a rounded blotting pad which is an item for which all those waste pieces of mahogany, walnut, etc., can be used. This article, when finely varnished and finished, retails at from $1.00 to $1.50. Fig. No. 3 is a doll's table which can be made with a small amount of work of any wood, the retail price ranging from 25 cents to $2.00 for the larger sizes. Fig. No. 4 is a pipe rack, a novelty which will find a place in nearly every home. It is made about 12 inches long and 3 inches wide and. if nicely finished, this article will easily bring $2.00 or more. Fig. No. 5 shows a book rack into which almost any kind of waste may be converted. The article will find a ready sale in the big department and book stores. The construction is simple, being generally made 18 inches long with the ends 6½ inches wide and 6 inches high. This article may be easily retailed at from $1.00 to $3.00, and every home in the country is a possible prospect for sale.

Thus, a whole array of articles could be shown which, with the addition of one or two machines to your plant, could be produced from the so-called waste at a good profit.

School Furniture by St. John Firm

Lordly and Son, St. John, manufacturers of furniture are busy at their St John, N. B., factory on an order for school desks for the St. John Board of School Trustees. These desks will be used in the new school being constructed in West St. John. This firm and Son have manufactured sixty per cent of the school furniture used in the St. John schools. They are also competing favorably with upper Canadian firms in the sale of showcases in St. John and adjacent territory. They now have a factory in the south end of St. John.

Emery's Furniture Works, Charlotte Street, St. John, N. B., have secured more floor space than formerly held in the Charlotte Street quarters, and have installed additional machinery. The factory has been in existance for many years, and business at the present stage is exhibiting a decided improvement. Tables, chairs, school desks and other items of school furniture, are manufactured.

This photograph was taken of our exhibit at the Indianapolis Industrial Exposition held in Indianapolis last fall, which was attended by more than 150,000 people. Our exhibit was pronounced the finest display of Hardwoods and Veneers at the exposition.

Business Paper Fundamentals Taught by Daily Newspapers

GLANCE through the pages of any great Daily Newspaper and notice how it tends toward Business Paper practice.

Here is a building section, there an electrical department, again columns of interest to wholesaler, a lumber page, a theatrical page, a sporting page—and next to each you find the advertising relative to the subject in question.

Watch the reader turn to the department in which he is most interested—where the advertising is to be found which will be most likely to appeal to him. So with the business man—as a time-saver, he takes up his business paper to learn the latest developments in his special field. Other publications have but a casual interest for him—because they broaden his general knowledge or afford mental relaxation—but it's the business publication he desires, and requires, when he's thinking of business only. He knows that the business paper will give him the very facts he needs—briefly and **reliably**—in both editorial and advertising pages.

To advertise in business publications places your products before such business men at a time when they're thinking of business.

How Case Hardening Was Overcome

An Electrical Concern Using Air-Dried Lumber Experienced Trouble Due to Case Hardening Which Was Satisfactorily Remedied by Seasoning the Stock in a High Humidity Dry Kiln

A large manufacturing electrical concern purchased a quantity of quarter-sawed red oak which was to be used in one of their products. This was the average air-dried lumber—that is to say, the wood was dried in the open by the natural atmosphere. It was found, however, that the finished electrical device was very erratic in operation and that there was considerable distortion. On investigating, it did not take very long to find the trouble. The lumber used showed a very poor condition of drying. Samples were then taken by experts and laboratory tests were made. To make such tests, the wood is usually cut roughly like a tuning fork.

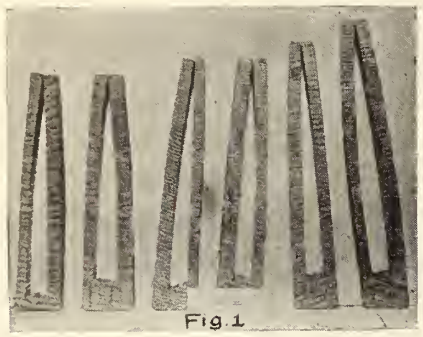

Fig. 1 —Case hardening is indicated by the closed prongs

Figure 1 shows what happened to the testing samples after being left in the laboratory for a few days. The samples were cut from the lumber exactly as it was delivered from the mill. It will be noticed that in every instance the tines of the fork closed together at the top. The cause of such distortion is what is known as "case-hardening."

When any kind of lumber, whether red oak or not, manifests this condition, it is indicative of overdrying of the surface of the wood, the inner portions hardly being affected at all. Case-hardening will, in every instance, curve the test fork towards the top. This is due to the unequal stresses of the lumber which is dried to hardness on the surface, yet hardly fit for use immediately below.

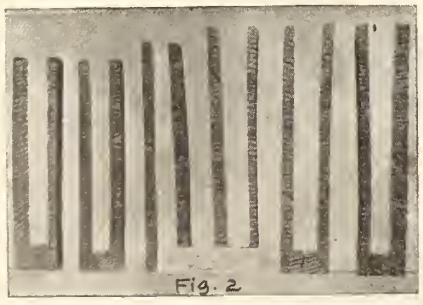

Fig. 2—Case hardening cured by proper kiln drying

Case-Hardening Overcome

With all this lumber on hand, the electrical concern had to do something to remedy conditions. Usually, case-hardening lumber is somewhat hopeless of recovery but the wood was put into a well-known high humidity dry kiln to see what benefit could be obtained. The result was not only gratifying but indeed surprising. Figure 2 shows the same samples after they were taken out of the kiln showing the tines approximately parallel. This is correct and normal condition of test samples of properly dried and seasoned lumber.

As the samples showed up so well, all the lumber was put into the kiln. From time to time, tests were again made and in every instance, it was found that this dry kiln was able to rectify a rather bad example of the case-hardening of wood. The electrical company was, therefore, able to use the wood which naturally saved the concern a good deal of money, as the lumber was purchased as air-dried stock which in reality it was.

The saw-mills can hardly guarantee the condition of lumber, but they can promise that any particular lot has been left out in the air for several months. What the wind, weather and sun does to it can not be controlled by the seller.

The buyer sometimes takes a chance and for all ordinary purposes, the air-dried stock is plenty good enough. But where special care must be exercised as in electrical apparatus, the lumber must be free from all danger of warping, shrinking or swelling.

Woods Used for Turning

In selecting woods for lathe-turning purposes, the nature or use to which the object turned is to be put, appearance of the finished product and the ease with which it may be worked are prime requisites. To illustrate this thought: Maple is ordinarily used for turning tool handles; poplar and hard maple for household articles, such as potato mashers and rolling pins; pine, gum, and poplar for glove and stocking darners; hard maple for rammers and mallets; maple, cherry and gum for dumb-bells and Indian clubs; mahogany, cherry and walnut for gravel heads and handles; any soft wood for rosettes; poplar and cherry for pin trays; cherry and birch for card receivers; woods that take polishes for desk trays; maple and birch for bread plates; close-grained wood for sewing rings and towel rings; close-grained hardwoods for round picture frames and napkin rings; maple, mahogany and cherry for artistic boxes; white pine for rope pulley patterns and patterns of other descriptions; cherry, mahogany and redwood are also generally used in pattern making, although white pine leads the class; poplar for turning when followed by considerable bench work; gum and walnut for ring stakes and jewel trays; mahogany for low stools, candle sticks, floor lamps, etc.

Old fashioned virtues still bring substantial rewards. For instance, another man has been discovered who made his fortune by attending to his own business.

The Lumber Market

Domestic Woods

There seems to be a well-defined impression in manufacturing circles that hardwood lumber may be scarce next spring. Stocks in several lines are none too plentiful and those who have quantities on hand are holding out for comparatively high prices. The demand for maple at the present time is particularly active and the inquiries that are coming to hand for various other woods indicate that woodworking establishments and wood-consuming industries are entering the market for supplies and preparing for the renewal of activity which is apparently at hand.

There is a quiet confidence that the hardwood situation, which has grown firmer during the past month, will continue to develop in strength and volume. It is admitted that the complete rehabilitation of the industry has been delayed first by the coal strike and later by railway shop crafts' disputes, causing car congestion at many points, embargoes at others and a slowing up of distribution processes generally. Agricultural implement firms are now operating, piano manufacturers are getting busier, the better class of furniture is moving more freely, and automobile concerns were never rushed in September as they are this month. All this means continued activity in the hardwood arena.

One complaint heard from producers and wholesalers is that the low ends of certain woods are difficult to dispose of, in fact are a drag on the market. It is likely, however, that some avenue will be found in the near future whereby No. 3 common may be employed.

Shipments of Canadian hardwoods to the other side have been quite heavy of late and stocks of birch and maple are moving. The continued building boom in larger centres is causing a certain amount of interior trim to be called for. Other projects in the building line which have been held in abeyance awaiting the outcome of the abundant harvest, will now proceed. Hardwood flooring manufacturers have been exceptionally busy, some of them reporting that last month was the largest in their history.

With the resumption of transportation facilities, it is expected that the hardwood trade, which the strikes have retarded to some extent, will soon find its natural flow on account of the outward movement of manufactured lumber being more or less restricted for some weeks. With big consumers the demand has continued as they were evidently not willing to take chances on a serious tie-up. The market has been searched for stock and nearly everything suited for their requirements has been corralled. In most cases buyers have demanded that shipments be made immediately.

Imported Woods

As we go to press the lumber market in the United States is featured by a very satisfactory demand in most centres but very unsatisfactory shipments owing to the car shortage coming in the wake of the railroad strike. The problem of hardwood manufacturers for some time to come is that of production and distribution. A shortage of flat cars is preventing the transportation of logs to the mills, and in some cases mills have closed down altogether because of inability to secure logs. Because of the doubtful transportation, logging itself is slowing down in some centres, which not only affects the immediate supply but also the supply some time hence. The logging firms which depend on water or their own logging equipment for transportation, have little to fear, but those that are dependent on the public carriers are receiving extremely poor service.

The curtailment of transportation facilities is also affecting the distribution of lumber from the sawmills, and were it not for that, the mills would be able to dispose of all the stock they could manufacture as the demand appears to be quite considerable in extent.

Prices seem to be holding firm with a slight tendency upward on account of the difficulties in filling orders. The hope of the hardwood manufacturers is that an early settlement of the railroad strike will enable them to cope with the demands that are coming in and thus sell at prices no higher than those which have been prevailing for some time.

Memphis, Tenn.—Reports from this centre indicate that demand is steadily increasing and that the volume of business in hardwood lumber will be limited only to the available supply of lumber and the available supply of cars. All firms engaged in the hardwood business in this territory are finding plenty of orders for all the lumber they have ready for delivery, but they are seriously handicapped in meeting the demand by the pronounced shortage of cars. Flooring manufacturers are very active and are using quite a great deal of No. 1 and No. 2 common oak, while other building trade interests are buying in fair volume though, perhaps, not quite as heavily as recently. Some furniture manufacturers are stocking up lumber and automobile firms are buying fairly heavily in certain lines. The export trade is reported to be greater than at any other time this year.

Louisville, Ky.—The hardwood demand in the Louisville territory appears to be fairly active although many operators are not able to accept new business or promise anything in the way of delivery. Stocks that are available are being rapidly picked up but there is a tendency to wait on the part of some buyers until the strike situation clears itself. Prices are reported to be quite firm with a tendency to go a bit higher.

Evansville, Ind.—Trade would be very satisfactory but for the railroad strike that has created a car shortage. When this impediment is settled it is felt that business will resume on a very active scale. Lumbermen say that the whole state of the fall and winter business now depends upon how soon the strike of the railroad shopmen ends. Few of the large hardwood mills are being operated at this time. Stocks are low in many sections which leads to the belief that after the demand for lumber picks up, there will be a gradual increase in prices.

Victor Woodworking Company of Amherst, N.S., has been conducting an intensive advertising campaign in the maritime newspapers, and this has resulted already in an improvement in business. This concern manufactures floorings, doors, sashes, tables, sheathing, clapboards, ornamental woodwork of all descriptions. This firm also manufactures cabinets, having a planing mill and cabinet factory at Amherst. Church, bank and school work are especially catered to.

Warren Manufacturers, Saskatoon, Sask., were recently awarded the millwork contract for the new collegiate institute. The new building will cost about $126,000 and is being built by the school board of Saskatoon.

Refrigerating Engineers, Limited Montreal, were recently granted a federal charter, with a capital of $50,000, to take over the Frick Ice & Refrigeration Company and to manufacture and market refrigerators of all kinds.

Ford Company of Canada, Ltd., Ford, Ont., are preparing plans for the erection of a new automobile plant on Danforth Ave., Toronto. The building will cover five acres and the dimensions will be approximately 400 x 500 feet.

Andrew Gray Company, Limited, Toronto, have been granted a federal charter to take over the Andrew Gray Company, Limited, Owen Sound, Ont., and to manufacture and market all kinds of furniture. Capital $50,000.

Canadian Ruler and Wood Advertising Novelty Co., Limited, Toronto, have recently obtained a federal charter to manufacture and market all kinds of wooden novelties. Capital $100,000.

Frank E. Windsor, manager of the London, Ont., branch of the Nordheimers Piano and Music Co., for fourteen years and recently connected with William McPhillips, Ltd., has been appointed manager of Heintzman and Co., at London.

Geo. Lebel, 201 Baby St., Montreal, was awarded the millwork contract by the Catholic School Commission, North Dist., for their new girl's school and residence, to cost $180,000.

Buist McIntosh Company, Ltd., Orillia, Ont., have been incorporated to acquire the business of Buist and McIntosh and to make and sell refrigerators, ice cream cabinets tubs and other wooden storage equipment. Capital $50,000.

The Canadian Pipe Company, Vancouver, B. C., are contemplating the erection of a new wood pipe factory which will cost $35 000. The old plant was recently destroyed by fire.

The Montreal Pattern Works, 242 Clark St., Montreal, Que., have added to their plant, and are now turning out store fixtures, wood turning and carving as well as furniture repairing.

Morin & Tremblay, Limited, Roberval, Que., were lately incorporated to manufacture and market all kinds of wooden boats. Capital $49,900. R. Morin and E. E. Tremblay, manufacturers, both of Roberval, Que., are two of the incorporators.

The Henry Wise Lumber Co., of St. Catharines, Ont., report that they have had the busiest year so far in the history of the firm and believe that trade will continue to be satisfactory especially if the farmers get a good price for their produce.

Canadian Sidway Company, Ltd., Toronto, has been granted a federal charter to manufacture and market push carts, sleighs, carriages and all kinds of children's vehicles. Capital $165,000. Frank R. Hodgins of Toronto is one of the incorporators.

In a letter to the Board of Trade, Woodstock, Ont., the Brunswick-Balke-Collender Company recently notified the city council that they would not locate their Canadian headquarters in Woodstock. The statement is a disappointment to the city, which has in the last three years spent large sums of money in securing property for the proposed plant.

Riviere-du-Loup Auto Co. Ltd., Riviere-du-Loup, Que., were recently granted a provincial charter with a capital of $50,000, to manufacture wagons, carriages, automobile bodies and other wooden vehicles. Two of the incorporators are A. Berube and Joseph Mercier, both of Riviere-du-Loup.

Bromsgrove Guild of Canada, Ltd., Montreal, have been awarded the contract for the furniture equipment of the

Uniform Lumber Means Greatest Satisfaction To The User!

You no doubt have experienced the expense, loss of time, and loss of materials, caused by the use of improperly cured, wrongly graded, and carelessly handled hardwood.

Kraetzer-Cured Lumber is absolutely uniform in quality, properly graded, and every board plainly marked, showing the grade. To show our faith in Kraetzer-Cured products, every board is stamped with our brand.

THE KRAETZER-CURED LUMBER CO.

Because of our unusual facilities we control the lumber from the virgin growth to the time it is loaded on the cars and shipped to you.

When you have once used Kraetzer-Cured Lumber you will not be satisfied with the ordinary kind. Read the eight important reasons why Kraetzer-Cured Gum is used by thousands with such satisfactory results. It will give the same results to you.

Kraetzer-Cured Lumber is of the very best quality, carefully handled by all departments. Every step in this process is taken with the idea of producing uniform high grade hardwood that w ill give maximum service in your hands.

In addition to Kraetzer-Cured Gum, we can furnish Oak, Ash and other Southern Hardwoods.

The Kraetzer-Cured Lumber Co.

GENERAL OFFICE: GREENWOOD, MISS.

Band Mills: Greenwood, Miss., Moorehead, Miss. Leflore, Miss.

You Should Use KRAETZER-CURED GUMWOOD *Because:-*

1. It is STRAIGHT and FLAT, free from the warp and twist usually encountered in untreated stock.
2. It is BRIGHT and will satisfactorily take any finish.
3. It is free from dote or rot—the sap and gums are eliminated by the steaming process, and fermentation and decomposition are thus prevented.
4. Through the elimination of stain and decomposition, it possesses greater strength and longer life.
5. It contains only atmospheric moisture, enabling it to be used for many purposes without kiln drying.
6. When kiln drying is necessary, this can be done in much less time and with more satisfactory results.
7. It is uniform and dependable. One car like another, grade and measurement what it should be—no time w a s t e d in reporting complaints or shortages, no delays or interference with factory schedules because of holding lumber for adjustments.
8. It is the most economical lumber available. It will satisfactorily answer any requirements expected of materially higher priced woods. Join our little army of satisfied users, and just as peace is about to supplant war, let peace of mind take the place of the warfare and worries that usually beset the user of lumber.

We're proud of this product —that's why.

new bank building to be erected for the City & District Savings Bank, St. James St., Montreal. Alf. Mercure & Fils, Montreal, have secured the millwork contract for the same building.

Walker Company, St. Thomas, Ont., is a new concern incorporated to manufacture a liquid glass finish for finishing furniture. The company is busily engaged organizing its sales territory. The headquarters are in the Spohn Block, Talbot St. West.

J. Crawshaw, of the Amherst Cabinet Works, Amherst, N. S., has accepted the position of woodworking instructor in Sackville at Mt. Allison. Mr. Crawshaw was owner of the Amherst Cabinet Works, which business will now come to a close with his departure from Amherst.

The proposed regulation of the railway commission in ordering that all cheese boxes be wired is meeting with a storm of opposition from many interested parties. It was stated by the Brockville Board of Trade that if the regulation took effect it would add 16 cents to the cost of each box.

Sonora Phonograph, Limited, Toronto, have been granted a federal charter to manufacture and market phonographs and other musical instruments. Capital $40,000. E. D. Coots, of New York City and I. Montagnes, of Toronto, are two of the incorporators.

The Art Craft Furniture Company, Goderich, Ont., a recently organized furniture manufacturing concern, is remodelling an old factory and installing some new machinery equipment. The company is also interested in prices of raw materials in quantity.

W. A. Murphy, of Norwood, Ont., recently started a retail lumber yard and sash and door factory. His plant is well equipped for producing woodwork of all kinds. Mr. Murphy reports that business with him has been very good so far this season.

The Gun-son-ola Company, Limited, Wingham, Ont., have been granted a provincial charter with a capital of $150,000 to take over the business carried on by William Gunn and to manufacture and deal in musical instruments and furniture. W. Gunn and C. Gunn, both of Wingham, are two of the incorporators.

Mr. Thos. Burridge, of Brockville, Ont., who is well known in woodworking circles, has recently opened a woodworking plant equipped to manufacture camp stools, kiddie cars, hand sleighs, rocking chairs and toys of every description, also chesterfield frames and chairs and cabinet work of all kinds.

The Brantford Novelty Company's plant, Brantford, Ont., recently suffered a loss of $1,500 when their building took fire. Much machinery and unfinished work was damaged owing to the inflammable character of the materials manufactured. The plant was very busy at the time and the delay will cause considerable loss.

Steven & Groff Lumber Co., Beamsville, Ont., was recently incorporated to manufacture and deal in all kinds of builders' supplies. Capital $40,000. J. A. Stevens and E. G. Groff, both of Beamsville are two of the incorporators.

Piggott Lumber Co., Windsor, Ont., have started excavation for a two storey brick addition to their lumber shed at a cost of $5,000.

The Hayes Wheel Company of Canada, Ltd., Windsor, Ont., according to a statement made by manager R. B. Craig, will shortly co-ordinate their operations in Chatham, Ont. Mr. Craig stated that formerly the wooden part of the Hayes wheel was manufactured in Chatham, but this plant will be moved to Windsor where the two sections of the company will be housed under one roof.

The Preston Woodworking Machinery Company, Ltd., of Preston, Ont., brought out an interesting little folder recently, gotten up especially for distribution at the Canadian National Exhibition in Toronto, which illustrates several of the company's extensive line of woodworking machines, including planers, shapers, band saw, rip saw, tenoning machine, moulder, saw and jointer guards, motor driven cut-off saw and swing saw, saw tables, boring machine, lathes, jointer, etc.

A. McN. (Sandy) Staples, for the last sixteen years head of the retail department of R. Chestnut & Sons, canoe and sports goods manufacturers, of Halifax, has severed his connections with that firm and will become representative in Nova Scotia and Newfoundland for P. W. Bird and Son, building material manufacturers of Hamilton, Ont. Mr. Staples was presented with a handsome amber pipe by the members of the staff. The firm of R. Chestnut & Sons, through W. T. Chestnut, managing director, expressed appreciation of Mr. Staples' services and presented him with a parting gift.

Haley and Son, St. Stephen, N. B., which firm also operates a mill on the Maine side of the St. Croix river at Calais, have been manufacturing automobile bodies of late in addition to the sashes, doors, tables, flooring, etc., recognized as products of the St. Stephen factory. Haley and Son have been advertising considerably for some time and business has been increasing in volume each year. Alterations and additions have been made to the St. Stephen factory to cope with the increased business. Harry Haley, the manager of Haley and Son, is one of the leading citizens of St. Stephen and is active in the affairs of that border community. He is a keen follower of sports and an incurable adherent of harness racing. Mr. Haley owns several horses and nothing pleases him more than to leap into the sulky and drive his speedy equines around the track at St. Stephen in a race or practice spin. He has won a number of races and finished well up with the winner in others.

The plant of the Christie Woodworking Company, Limited, Erin Street, St. John, N. B., is being operated steadily and by an enlarged crew of men. This firm is employing more men now than at any time during the past few years. At the present time the company is conducting an intensive advertising campaign in behalf of its products, newspapers, programs and circulars being utilized to present the case of the concern before the public. The Christie firm is one of the oldest woodworking manufacturing industries in the maritime provinces. The industry was started on City Road in St. John sixty years ago. Ten years ago, the plant was burned, and the firm rebuilt but after operating for two years removed to the Erin Street location. The City Road property is retained by the firm for the storage of lumber. The Erin Street factory was built seventy years ago, at the corner of Erin and Brunswick Streets, on the Courtenay Bay freight branch of the Canadian National Railways. It was originally built by Scott and Lewton, one of the pioneer woodworking firms of the maritime provinces. This firm went into the discard, about fifteen years ago, and the property was purchased by the Christie Woodworking Company, Limited. The location is an advantageous one.

Obituary

Joseph Lamarche, Montreal, for many years engaged in the sash and door business, died recently at his home on Hartland Ave., in his 73rd year.

John Fair, Arthur, Ont., who for many years conducted a woodworking business at Arthur, recently passed away. As a boy the late Mr. Fair came to Canada from Ireland and learned the wagon making business. He always took a great interest in the affairs of his town and his passing is mourned by a wide circle of friends.

The Sturtevant story is in the last paragraph of this letter; but read the whole of it—it is mighty interesting

Attention -Mr.H.M.Nichols,
M'g'r-Convey'g & C.I. Fan Dep't.

Gentlemen:-

The writer has just returned from the Webster Furniture Company,Inc, Rochester,N.Y.and wish to advise that the 70" and 35" electric steel plate planing mill exhausters arrived in due time and we have everything ready and connected.

We wish to taank you for the prompt service and the manner in which you handled this shipment and we asure you that we appreciate it very much.

The design and workmanship of your apparatus is A #I.and in the writers' opinion can not be beat. It is a pleasure to sell such equipment for I asure you that I feel rather proud of this job.

We followed your instruction in re-assembling the 70" planing mill exhauster and we got this so we could spin the fan wheel with one finger ,they did not have the motor wired so we could try it but they will have in a day or two.

All the fans that you have furnished since we started in business have given us no trouble we have never heard a complaint from any of the customers but all have pronounced it " a perfect job " ,

The customers do not hesitate to pay more money for your apparatus after it is proven to them that the design, construction and engineering is A #I.

Thanking you again for past favors, we are

Yours very truly

POSITION VACANT

Wanted in a progressive Canadian town within 100 miles of Toronto, Ontario, a competent experienced detailer and biller for large millwork factory. Young man preferred with proper qualifications. Answer by letter in own handwriting. State whether single or married and salary expected with all necessary references as to character and ability. Position permanent and working conditions exceptionally good. Address Box 140 Canadian Woodworker, Toronto.
8-9

For Sale

A going concern woodworking plant and retail lumber yard in Manitoba manufacturing sash, doors, store and bank fittings, could add furniture lines, big opportunity. Party retiring through ill health. Would consider revenue bearing property. Apply Box 143, Canadian Woodworker, Toronto. 9

ARTICLES WANTED

Floor Sander Wanted. State price, make and condition of same. Box No. 142, Canadian Woodworker, Toronto. 9

POSITION WANTED

as rod bill and detail man in a furniture factory by one who has held positions as foreman, superintendent and factory manager. Address Box 144, Canadian Woodworker, Toronto.

Lumber Men to Supply Trade Data to Public

In a letter to the newly-established Trade Associations Division of the Department of Commerce, Wilson Compton, secretary-manager of the National Lumber Manufacturers Association, places its whole statistical organization at the service of the government in such a manner that the public will have all the trade information that the lumber manufacturers compile for themselves as soon as, if not sooner than it is available for individual member manufacturers.

The purpose of the National Lumber Manufacturers Association in thus making available to the government and public without charge a statistical service that has been built up through many years at great cost is two-fold. (1) To give prompt and conclusive evidence that the subscribers of the association in the collection and dissemination of lumber trade information neither have nor desire any commercial advantages; (2) to pioneer the way for a general exchange of trade association industrial statistics, through the Department of Commerce, so that it may be possible to obtain an accurate current record of the industrial activities of America.

Scope of Statistics

Mr. Compton's letter gives the Department of Commerce exact information concerning the matter in which the National Lumber Manufacturers Association collects and distributes lumber trade information, which consists of weekly statistics of the softwood lumber movements, giving the production, shipments and orders and changes in stocks as reported by eight regional associations, a quarterly graphic lumber summary and a monthly graphic summary of general business statistics.

It is the conviction of the National Lumber Manufacturers Association that if the Department of Commerce chooses to act favorably on its offer to complete statistical co-operation with the government, other great industrial associations will follow suit, with the result that it will be possible to present to the business world periodically an accurate current statistical picture of the commercial movement of the country. It is hoped that such information, wisely diffused, will help to avoid the excesses of industrial activity which are one of the great contributing causes to alternating periodical business depressions.

BLACK BROS.
CLAMPS

Where Black Bros. Clamps are known, there is no second choice. Know them.

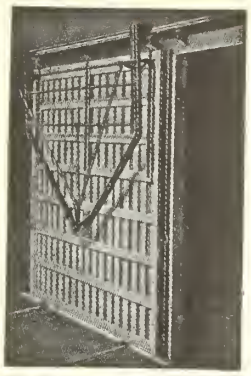
The Door Carrier System



Makes your dry-kiln doors steam-tight and saves time, heat, trouble and money.

Carrier lifts door clear of kiln and carries it down track. Returning, deposits door to rabbeted joint, where it is held steam-tight by its own weight. Applicable to old or new kilns.

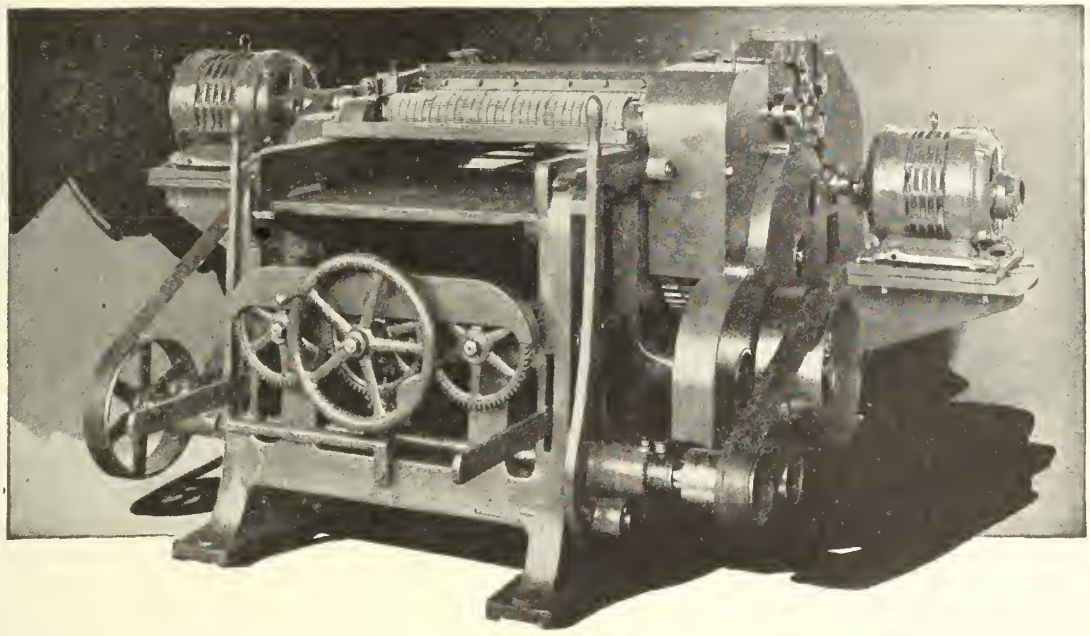
SKF



Deep-Groove Ball Bearings
Maintain Cutter-Spindle Settings

ACCURATE planing at high speed is largely a matter of maintaining the correct setting of cutter spindles. If bearings wear, poor workmanship results; if they bind and heat, production is retarded.

But supported on deep-groove ball bearings—properly installed and mounted—vibration is eliminated, the cutter spindles maintain their original setting indefinitely and the bearings show no appreciable wear through years of service. For ball bearings do not absorb power in destructive friction which necessitates frequent and expensive renewal of the linings of plain bearings.

To say that a good planer can be made better by equipping it with deep-groove ball bearings, as made by the Canadian SKF Company Limited, is to state a fact established by experience.

—And Dietz Desks Are Sanded With Carborundum Brand Garnet Products

An office desk can be made "a thing of beauty and a joy forever" as well as a highly necessary adjunct to commercial life.

The J. F. Dietz Desk Company of Cincinnati, for forty-one years makers of fine desks, has proved this long ago. This concern makes office desks that are, in a sense, inspirational in their graceful lines, in the beauty of their woods and above all in the splendor of their finish.

There is a feeling of pride in our knowing that Carborundum Brand Garnet Paper and Cloth do a big share in the producing of these desks of quality.

Carborundum Brand Garnet Paper and Cloth are used on their disc and drum sanders. And the hand-finishing too is done with the Carborundum Brand Garnet Paper.

Quality and finish are characteristic features of any Dietz Desk. For the latter they look to Carborundum Brand Garnet Products—and they do not look in vain.

In such big plants and in little plants too
you will find that

CARBORUNDUM BRAND GARNET PRODUCTS MAKE GOOD SANDERS BETTER SANDERS

Morgan No. 6 Nailing Machine

MORGAN
NAILING MACHINES
Used in Nailing Wooden Toys

Many manufacturers of American Wooden Toys use our machines for driving 5/8" to 1 1/8" nails. Machines are adjustable in operation and can be adapted to any kind of nailing work.

If you are driving nails by hand, in making boxes, crates, toys, any woodenware articles, figure the cost. It is expensive.

Then send us samples of your work. Get an estimate of the cost of nailing on a Morgan Nailing Machine. Compare the figures. We'll leave the rest to your judgment.

Send us your nailing problems. We shall be pleased to give them our careful consideration and advise you regarding equipment for handling them. We invite your inquiry.

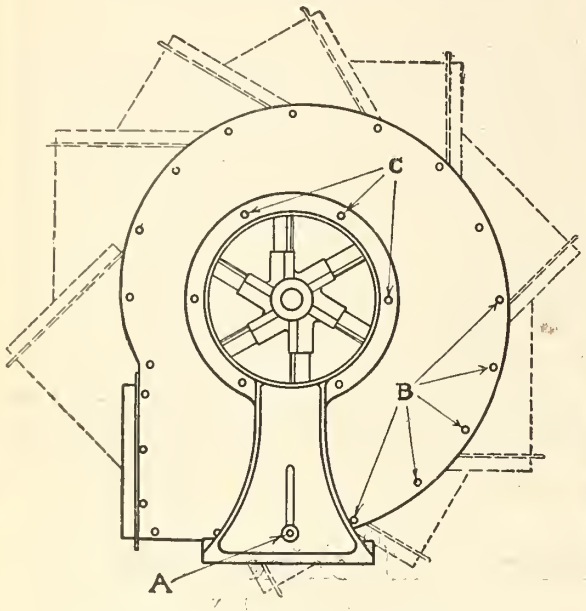
Canadian Mill Exhausters



One of the features of the Canadian Planing Mill Exhauster is the reversible housing. It is easily adjustable to either hand and to any discharge.

By this arrangement one fan may be used to meet all requirements, thus eliminating crossed belts and sharp angles.

Let our engineering department help you plan your refuse exhauster system.

"OLIVER"

Self Contained JIG SAW

Features—

1. Self Contained
2. Simple Design
3. Few Parts
4. No Springs
5. No moving parts above saw blade
6. Increased Efficiency
7. Reduced Vibration
8. Tilting Table
9. Quick in operation
10. Smoother Work

Think of it—no vibrating or moving parts above the saw blade—not even a spring—Sounds unreasonable—impossible. The proof is in the unexcelled operation. It does superior work with less power and in less time.

Send for circular of this or of any "Oliver" Woodworking Machinery.

Oliver Machinery Co.
Grand Rapids, Mich., U.S.A.

Cross Sectional View of Planer Knife. Shaded portion indicates the High Speed Steel Edge "welded" to the face of the knife.

Users of Ordinary Thick Knives Can Now, by the Simonds New Method of "Welding" Obtain the Same Cutting Efficiency that Users of Thin High Speed Steel Knives Secure

It has been an accepted theory that high speed steel knives could not be welded. Yet here it is by the new Simonds process welded to a soft metal backing. This allows us to heat treat the knives to bring out the utmost in cutting efficiency. Old style high speed steel knives cannot be heat treated because the braze will come apart like any other soldered article. Welded knives do not come apart. They give longer service and last longer. We can now furnish these "welded" high speed steel knives for Spoke, Moulding, Lathe, Chair, Jointer and Planer Knives up to 30 inches long. We know of no other knife manufacturer that can supply these welded knives. The price is the same as for the ordinary brazed high speed steel knife. Book your orders now.

New Model "D" Mattison Automatic Shaping Lathe at Rockford Desk Co.

Today, the up-to-date plant is replacing its old-style automatic lathes with the new, more efficient model for the same reasons they are replacing old-fashioned planers and saws with modern equipment.

SOME people, even though they have a turning machine, still think of the modern automatic lathe as a more or less special machine, adapted for the large plant making turnings by the thousands.

The fact is that for the average manufacturer of furniture ornamented with turnings, the Mattison Lathe is just as standard as a planer. Often more money is spent for turnings that go into production than for planing the lumber that goes into production.

Who would think of continuing the use of an old-fashioned planer when a new, more modern one would do the work at half the cost and much more accurately? For the same reason, he should also consider the New Model D Lathe.

Changing conditions in furniture manufacture have resulted in our redesigning the lathe and building it new from the ground up. It is easier and faster to operate, does better work, saves more material.

Even though you now have an old type lathe in operation, it will be worth your while to investigate the production possibilities of this New Model.

There is only one Mattison Lathe and only Mattison builds it

Specialists in Wood Working Machinery

All you ever knew about a Lumber Kiln is out of date. You can't select today the best kiln from past experience. Your best friend's advice wouldn't be any better.

You owe it to yourself to investigate the results obtained from Cutler Kilns. For the last two years our customers have been drying lumber in half the time required by the best of other kilns — and getting better lumber.

We can furnish records of actual Kiln runs — or show you kilns in operation.

Either one will convince you of the wonderful improvements over the old methods. — Write Us.

All essential features of Cutler Kilns are fully protected by mechanical and process patents granted and pending.

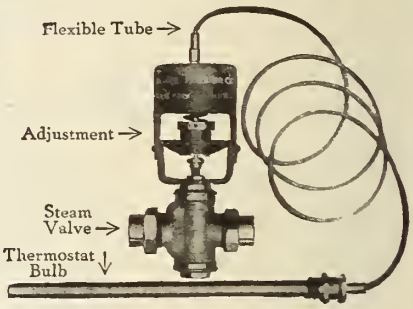
Controlling Heat For Industry

Powers Regulation, installed on any system of artifical heat, insures economy, safety, and the correct temperature.

Regardless of the kind of temperature to be controlled—whether of liquid or air —or for what purpose—there is a Powers Regulator specially adapted to that purpose—for controlling the temperature of a single room or an entire building—for vats—ovens—dryers—dyers—kilns —glue pots—varnish rooms—and many other places where heat control is necessary for best results.



The Powers Regulator No. 11

Specially adapted for the control of liquid temperatures as in hot water tanks, acid baths, glue pots, dye kettles, etc. Entirely automatic and self-contained, requiring no outside power for operation. Send for Bulletin 129. Other designs for other uses, wherever heat control is desirable.

Powers Regulators save time, conserve energy, protect material in process of manufacture. They are automatic, dependable, accurate.

Powers Regulation is the result of more than 30 years of labor in this one field. Let us help you in meeting today's manufacturing problems.

——ACCURACY——

That's the main point in a Glue Jointer. It must make at machine speed joints so smooth and straight that they can scarcely be detected in the finished product. Such a machine is

YATES No. 213 Continuous Feed Glue Jointer

The 213 is adaptable to many other kinds of work as well as Glue Jointing, and has so proven itself. With a 213 short and narrow stock can be accurately jointed and glued together, thus saving these small pieces that otherwise would go to the scrap heap.

Our 30 page Glue Jointer Book is one of the most comprehensive books on Glue Jointing. Gladly Send you one upon request.

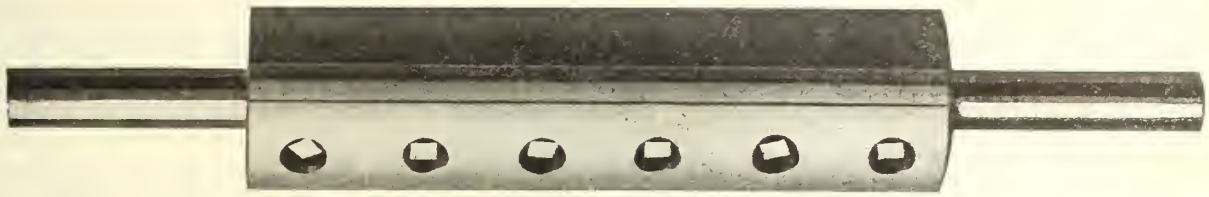
The Shimer Round Safety Cylinder with High Speed Knives



A Round Safety Cylinder that will Appeal to the Buyer and the User for three Reasons:

The first is our adjusting nut for setting the knives. It is the only cylinder with properly located adjusting nuts for setting the knives, which, with our way, can be set to 1-1000 of an inch.

The second is our way of holding the knife without tapping into the head.

The third is the correct angle of cut for the knives.

Made for Any of the Different Makers' Machines and in Any Length Cylinder.

In Stock For Immediate Delivery

1 New No. 8 Beach Rip and Cross Cut Saw Table, with 6" Jointer and Boring machine. A real portable Woodworker.
1 New No. 107 Crescent Woodworker,—26" Band Saw, Rip and Cross Cut Saw Table, 26" Bandsaw, Reversible Shaper, 12" Jointer and Boring Machine. All individually controlled. 5 H.P. to 7½ to operate.
1 Used No. 14 Sidney Woodworker, 27" Band Saw, Rip and Cross Cut Saw Table, 12" Jointer, Shaper, and Boring Machine, together with H.C. Mortising attachment, Planing attachment.
1 New Williams Variety Saw Table, with tilting table, raising and lowering mandrel. Cuts 2" above the table.
1 New 6 ft. Beach 6 stop Boxmakers Saw Table.
1 New Beach Tilting Top Saw Table, cuts about 3¼" above table.
1 Used No. 3 Beach Double Cut Off Saw, 6" to 80" between saws.
1 New No. 127 Preston Dimension Saw Table.
1 Used McGregor Gourlay Double Rip and Cut Off Saw, 72" between saws.
1 Used Clark Demill 3-side Planer and Matcher, 13", feed about a 100 feet a minute.
1 Used Cowan 24" Planer and Matcher.
1 Used M. 31 Cowan Dowel Machine, with ⅜", ½" and ¾" heads.
1 New No. 133-A Oliver 4" Bench Jointer, arranged for 25 cycle or 60 cycle operation.
Used 1 qt. capacity Glue Pots, no water or steam required, operate wherever you have a light variable heat.
1 New C.M.C. 12" Buzz Planer with round cylinder.
1 Used No. 44 Berlin 9 x 6 Double Cylinder Planer and Matcher.
1 Used Woods No. 110 Inside Moulder.
1 Used 20" Eclipse single surface Planer.
1 Used 26" Cowan Double Surfacer.
1 Used No. 177 Berlin Double Surface with divided rolls.
1 Used 26 x 10 McGregor Gourlay Double Surfacer, like C.M.C. 216.
1 Used 24" Cowan Double Surface Planer and Matcher.

We also have on our lists (not in stock at Toronto) a Mershon 54" Band Re-Saw, a S.A. Woods No. 401 15 x 6 Planer and Matcher, a No 91 Berlin 15 x 6 Planer and Matcher, a No. 34 Woods, 18 x 6 Planer and Matcher, and also a McGregor Gourlay QY 15 x 6 Planer and Matcher.

We will gladly send particulars of these machines on request

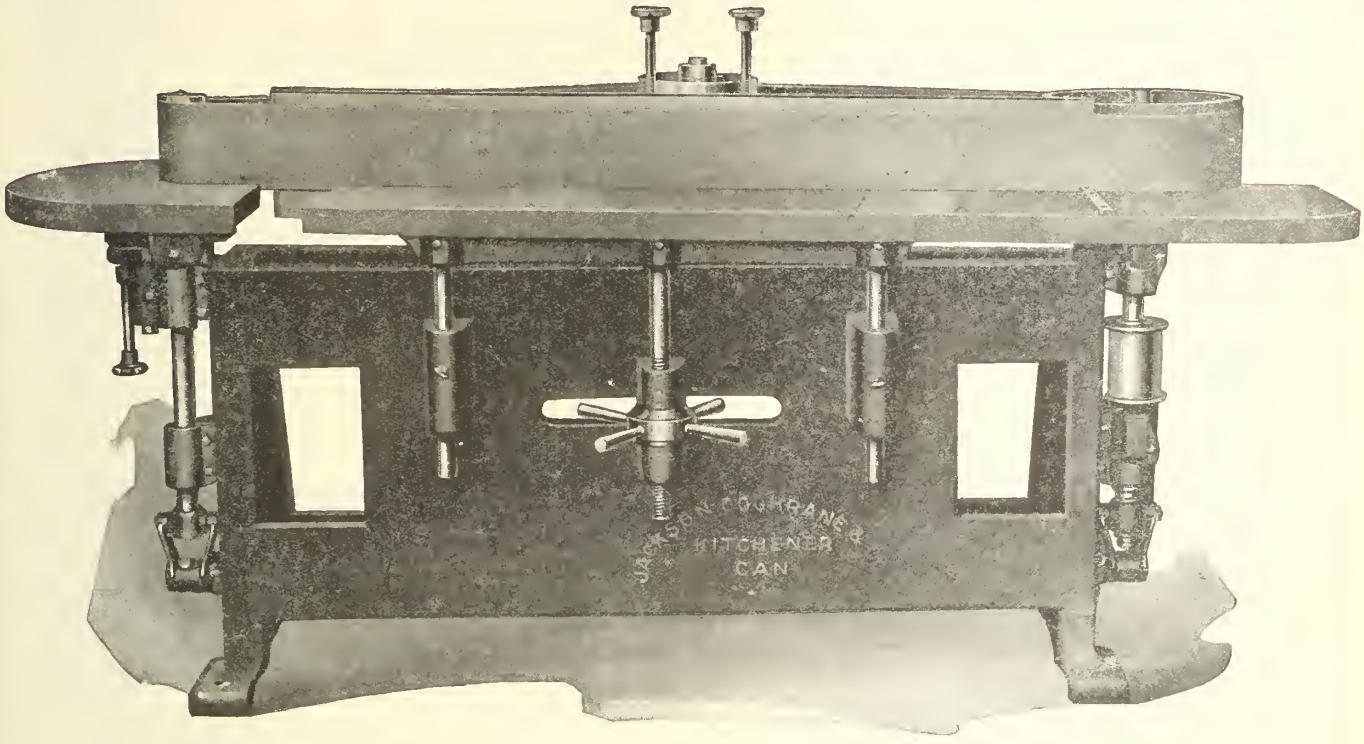
MATTHEW WYLIE & Co. Ltd.

81 PORTMAN STREET, GLASGOW

No. 272 Oscillating Belt Sander



No. 272. Oscillating Belt Sander for Edged and Shaped Work

This style of belt sander has a capacity several times greater than sanding drums or spindles. The high speed sand belt covers a long surface and retains its sharp and fast cutting properties. The long travel of the belt gives it an opportuntiy to cool off between contacts, whereas on drums and spindles, where the sanding surface is small, the wear is continuous and in one place.

It will also finish practically any piece of straight or bent work that can be supported on the tables or held against the platen or sanding rolls.

The design and construction eliminates all chance of vibration, thus insuring a perfect sanding contact. The tables provide an even and accurate support for the work, and as the belt travels with an oscillating movement, a perfect finish is assured.

The tables are the proper height and permit the operator to handle his work in a natural position. Numerous sizes of sanding rolls, special forms for shaped work and non-revolving sanding spndles may be used for sanding a large variety of work. The long platen between the sanding pulleys may be removed and replaced with special forms for any work having rounded edges.

This sander is so constructed that a number of stationary forms may be used for special work.

Features of Our No. 272 Oscillating Belt Sander

Heavy construction eliminates vibration.

Long belt surface prolongs life of sand belt.

Oscillating movement prevents scratch marks.

Belt pulleys covered with heavy coating of rubber provide a good driving surface and a perfect sanding cushion.

Large tables and each adjusted independently of the other.

S.K.F. ball bearings in small belt pulley.

Improved belt tightening device.

Convenience of operation.

Large capacity.

Very moderate price.

Large descriptive circulars now ready. Send for one and get full particulars on this Sander.

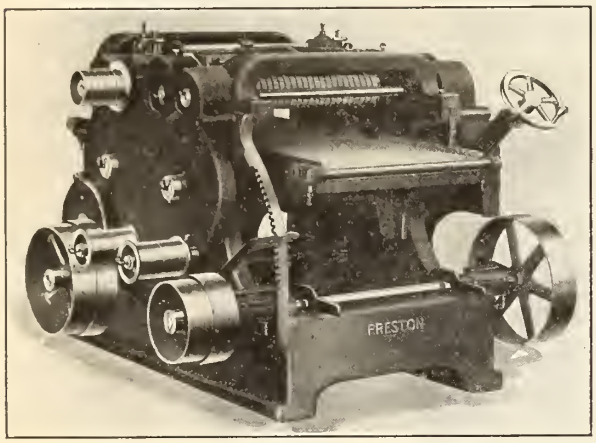
Specifications:

Large Sand Belt Pulley	14″ dia. x 8½″ face
Small Sand Belt Pulley	3½″ dia. x 8½″ face
Circular Table	25″ wide 11″ from spindle to end. 19″ long overall.
Long Table	72″ x 12″
Platen	60″ long 9½″ wide
Centre to centre of pulleys	72″
Idler Pulley	10″ dia. x 9″ face
Floor Space	8′ x 3′ 6″

Jackson, Cochrane & Company

Manufacturers of Woodworking Machinery. : KITCHENER, ONTARIO

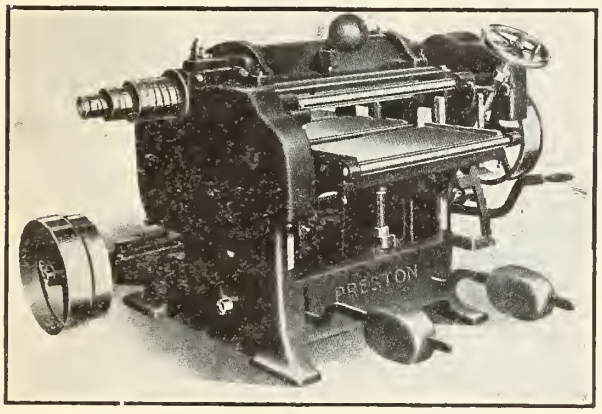
"Preston" Woodworking Machines Mean



No. 123 "Preston" High Speed Ball Bearing Surface Planer

This cut shows planer equipped with specially selected S.K.F. ball bearings, sectional roll, and sectional chipbreaker, round cylinder with four high speed knives, and arranged to receive Stockridge electric knife grinder and jointer. Cylinder speed, 5,000 R.P.M.

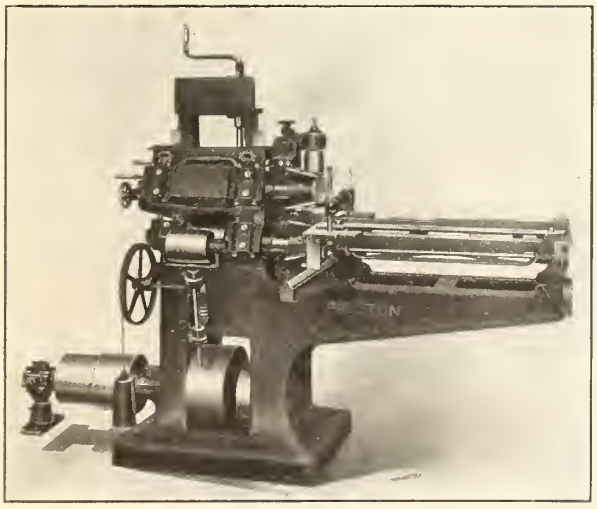
Two points are guaranteed: (1) It will reduce your sanding costs (2) It will increase your production.



No. 121 "Preston" Heavy Pony Planer

This cut shows standard machine. Can be built with:

(1) Straight roll or divided rolls or sectional roll and chipbreaker.
(2) Square cylinder or round 4 knife cylinder.
(3) Babbit Bearings or S.K.F. Ball Bearings.



No. 184 "Preston" Tenoning Machine

Features of Construction.

(1) Genuine Whitney self-lubricating bearings.
(2) Powerful belt drive.
(3) Large heavy base and very rigid in all parts.
(4) Practically all adjustments made from front of machine.

The Preston Woodworking

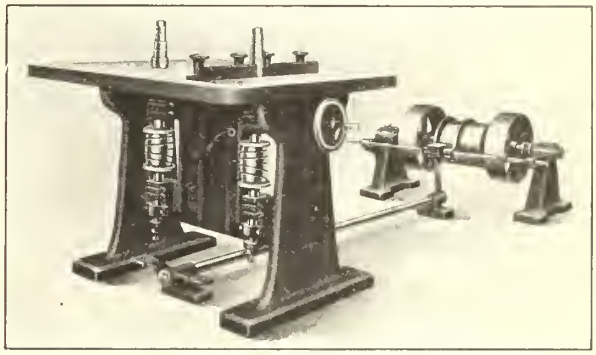
PRESTON,

We are Sole Manufacturers of and Agents in Canada for the Eaglesfield Patented Beltless Swing Saw

arger Output and Lower Expense

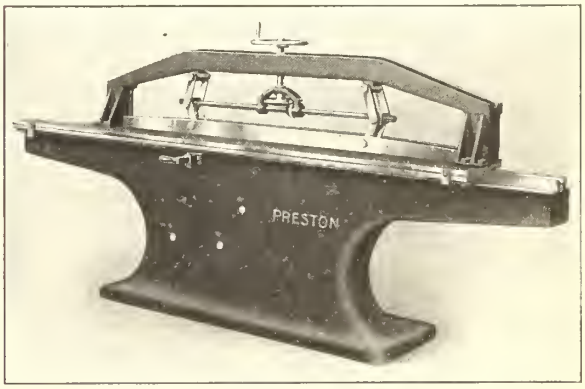
No. 164 "Preston" Ball Bearing Shaper

Designed to meet the requirements of concerns needing a lighter and less expensive Shaper than our No. 162.
Made with:
(1) Babbit bearings, plain countershaft.
(2) Ball bearings, plain counter-shaft.
(3) Ball bearings, special countershaft.



No. 181 "Preston" Veneer Jointer

The only veneer jointer that will effectively joint buckled veneer. Designed for the purpose of making commercially perfect face joints, butt or crosswise, as well as lengthwise of the grain on the highest figured Circassian Walnut or Crotch Mahogany Veneer. As rigidity is an essential feature of this type of machine, special care was taken in its construction. The frame, which is of cored section, is cast in one solid piece.



Eaglesfield Patented Ball Bearing Motor-driven Beltless Swing Saw

The special features of this saw are evident from the illustration. The motor is attached directly to the saw mandrel, which is supported in S.K.F. ball bearings. No belts or gears are used and the saw may be hung anywhere, regardless of the position of the shafting.

No. 132 "Preston" 36″ Band Saw

Made with or without guards. The wheels are all steel, covered with solid rubber bands, ¼ in. thick. Solid web lower wheel is supplied when desired.
We guarantee that breaking of saws will be reduced to a minimum on this machine by reason of our almost perfect tension device and style of guide.
Supplied with 3 H.P. motor for individual drive if desired.

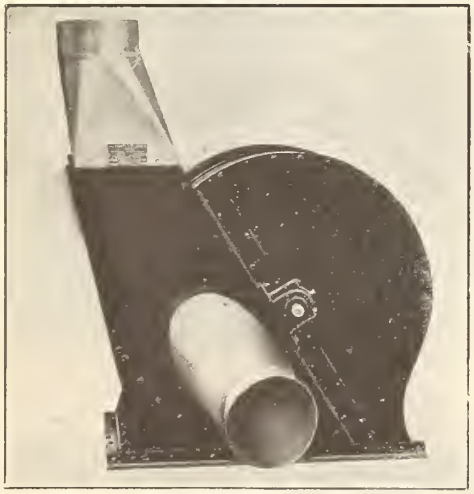
First Cost Vs. Final Cost

What does it cost to install a Blower System?



THE FOSTER FAN

is installed complete. No part of the installation is re-let. We have in our employ only the most skilled mechanics and all our work is erected by them. We assume the entire responsibility.

That depends.

The first cost of a job is not necessarily the real cost. A "cheap" or "low priced" installation may be very costly when you figure the trouble and additional expense through break-downs and replacements that very often occur.

A job done the "Toronto Blower" way means a good, lasting, satisfactory job. We stand behind our work and guarantee it. An expert engineer of extended experience will gladly estimate on cost of installation.

The Toronto Blower Company

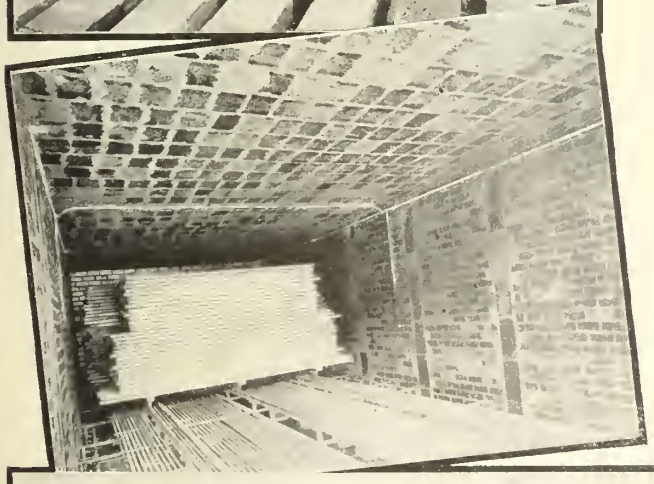
the GRAND RAPIDS VAPOR KILN

These views were photographed during construction and at completion of Packard Battery of 14 Grand Rapids Vapor Kilns designed and installed by us.

3,124 now in use in North America!



IF YOU are in the motor car or car body business it will interest you to know that Packard, Peerless, Pierce Arrow, Cadillac, Fisher Body, the Auto Body Company, Republic Truck and a score of other leaders in the automotive industry cure their wood in Grand Rapids Vapor Kilns.

If you make cameras, caskets, clocks, carpet sweepers, case goods, butcher blocks or zithers—the leaders in your line use Grand Rapids Vapor Kilns almost without exception.

Wm. Cramp & Sons cure lumber for ocean liners in our kilns. Curtis Bros. & Co. dry their famous interior finish in Grand Rapids Vapor Kilns. And so on without end! Complete endorsement everywhere because there is no other method that quite equals Grand Rapids Vapor Kiln results.

We maintain, as the very foundation of our continued leadership, America's most highly specialized and efficient laboratory service serving the woodworking industry. Technical bulletins covering practically every phase of wood curing problems are yours FREE upon request and the personal service of our corps of experts here and abroad is offered without placing you under the slightest obligation. WHEN consumers want kiln dried lumber and want it "right," they specify one of the many plants using.

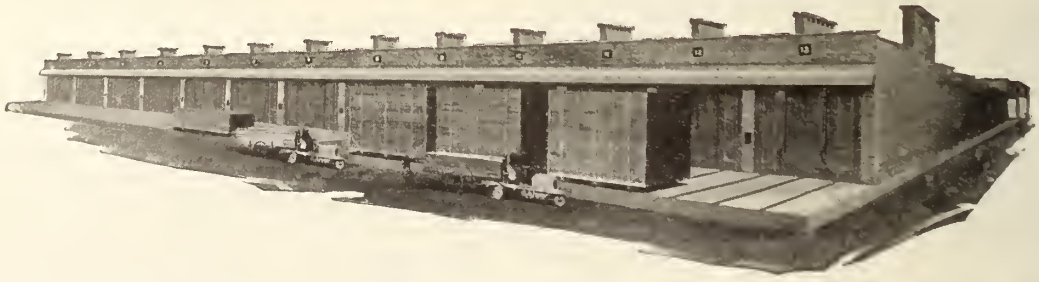
THE STANDARD
Dry Kiln — for Example



Thirteen New Standard Kilns at plant of M. B. Farrin Lumber Company, Cincinnati, O., which has used "The Standard" for years. They are the very latest in modern drying equipment. Installed by a firm widely known for the large amount and varied kinds of high-grade commercial drying which it does to the satisfaction of many kinds of consumers. If interested in drying get on our mailing list. Address The Standard Dry Kiln Co., 1542 McCarty St., Indianapolis.

1922 --- OCTOBER - NOVEMBER - DECEMBER -- 1923

Three Months Until the New Year Arrives

Are you ready for a Bigger and a Better year's Production?

NATIONAL AUTOMATIC HUMIDITY CONTROLLED DRY KILNS installed NOW will assure you perfectly conditioned lumber. They are the fruit of over twenty years' experience in the designing, operating and manufacturing of lumber kilns by the best dry kiln engineers obtainable. Nationals owe their success to the constant research made by these engineers, and the executing of improvements to meet the new phases in the scientific application of their findings, as applied to the practical use of kilns. As a result NATIONALS have become the most perfect, practical drying apparatus on the market.

When installing a National you are not experimenting,—all experiments have been made at our expense. You are guaranteed absolute satisfaction in the production of cured lumber of the highest quality.

Business is daily growing in volume and all indications point to better conditions. Are your dry kilns adequate to handle a bigger and a better production during the coming year? If not, NOW is the time to bring them up to the desired standard. Whether it is a question of new kilns or the remodeling of the old, our engineering services are free. Kindly write us full details as to your problems and we will be pleased to respond. This will not obligate you in any way.

Table made by Hastings Table Co., Hastings, Mich. Several of these tables went through the Pueblo flood undamaged, tho' under water for two days. Made with MONITE WATERPROOF GLUE.

Monite
Waterproof Glue

Endures Soaking, Steaming, or Baking

MONITE STICKS TO ITS JOB.

Withstood the Flood at Pueblo

"During the flood in Pueblo, Colorado, some of these tables in basements were entirely covered with water for a day. When they were taken out and wiped off they were sold as new.

"The ends, top and base are veneered. We use **Monite Waterproof Glue** in veneering up this table and have **never had any complaints about the gluing.**"

—Hastings Table Co., Hastings, Mich.
Letter of Oct. 25, 1921

Seldom does furniture or plywood have to undergo two days of soaking under water—but it does undergo changing conditions of moisture and heat with every change of the weather.

What flood-water does in a few hours, atmospheric moisture does in a few months or years—and then there is loose and peeling veneer and "dried-out" or "soaked-out" loosened joints.

MONITE WATERPROOF GLUE endures extremes of heat and cold just as it withstands immersion in flood-water. Plywood and joints glued with **Monite** endure—a point highy valuable to manufacturers of glue-made products, their dealers, and the buying public.

Monite Waterproof Glue panels have withstood 8 hours steaming, a week of soaking and all the baking that wood can stand.

Write for one of our small vest pocket panels of plywood made with **Monite** and test it yourself.

Two Definitions—Which Is Most Practical

FOR YOU TO USE?

Compo or Composition Carvings:—A puddy like compound made up of whitening, glue and rosin, is **not** immune to atmospheric conditions. Is **not** fiberous in nature. Has little or no grain. Is **not** sharp in detail. Can **not** be guaranteed against chipping. It is **not** immune to cracks due to expansion and contraction. Does **not** stain like **wood**. Should **not** be found on good furniture.

Keep up the spirit of the times, properly decorated furniture will always be in vogue. Do not kill Period Furniture by decorating the same with unreliable carvings.

"Fibro" Wood Carvings:—A reliable wood product. The result of years of diligent effort. Inspired entirely because of the short-comings of puddy carvings. Having all the grain effects of wood, sharp in detail, and truly artistic, all the qualities for absorbing stain and taking on a wood like finish. Last but not least a Canadian product.

Make Canada prosperous by buying Canadian products

Leg Carvings

Are superbly designed by leading craftsmen. The workmanship is strictly high grade.

Because we have a staff of skilled workers and the most improved machinery we are able to turn out excellent workmanship in large quantities on short notice.

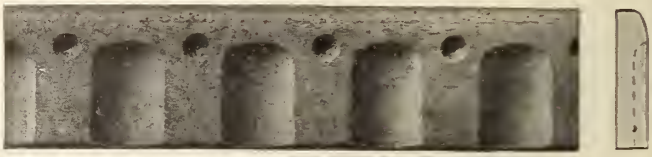
Our designing department is at your service. We will reproduce your own designs with perfect fidelity.

Write for full information.

S.E. OVERTON CO.
"Our Quality Is Always Higher Than Our Price"
ARTISTIC WOOD CARVINGS

South Haven, Michigan, U.S.A.

CARVED MOULDINGS, CARVINGS, CARVED LEGS

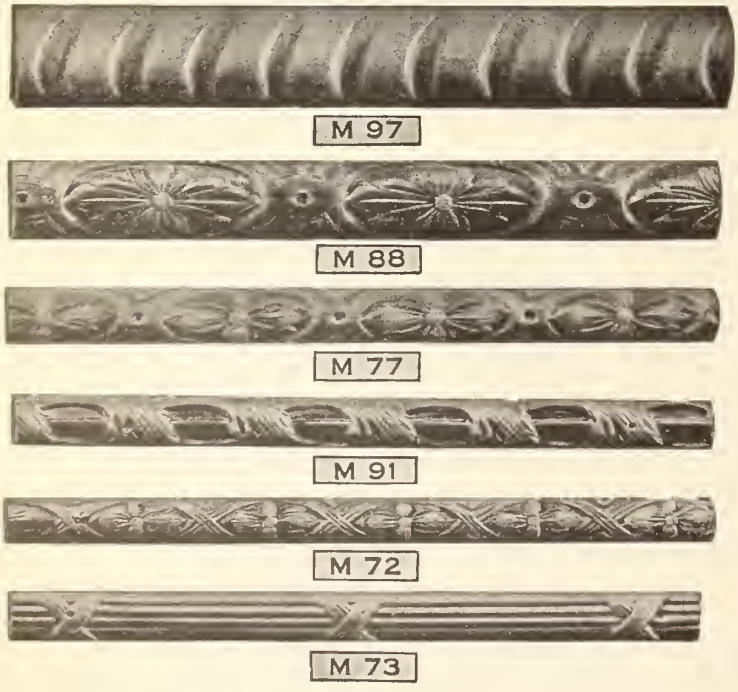


No. D-775 (Reduced One-Half)

No. D-763 (Reduced One-Half)

"KLISE" mouldings are carved, not pressed. Made in several hundred classic, period designs, in various sizes and shapes.
Catalogue of legs and samples of mouldings sent on request. Send us your designs or samples of carvings for quotation.

KLISE MANUFACTURING COMPANY
Grand Rapids, Michigan



MOULDINGS We are making more Period Mouldings than ever before. Orders should be placed early to assure your supply when needed.

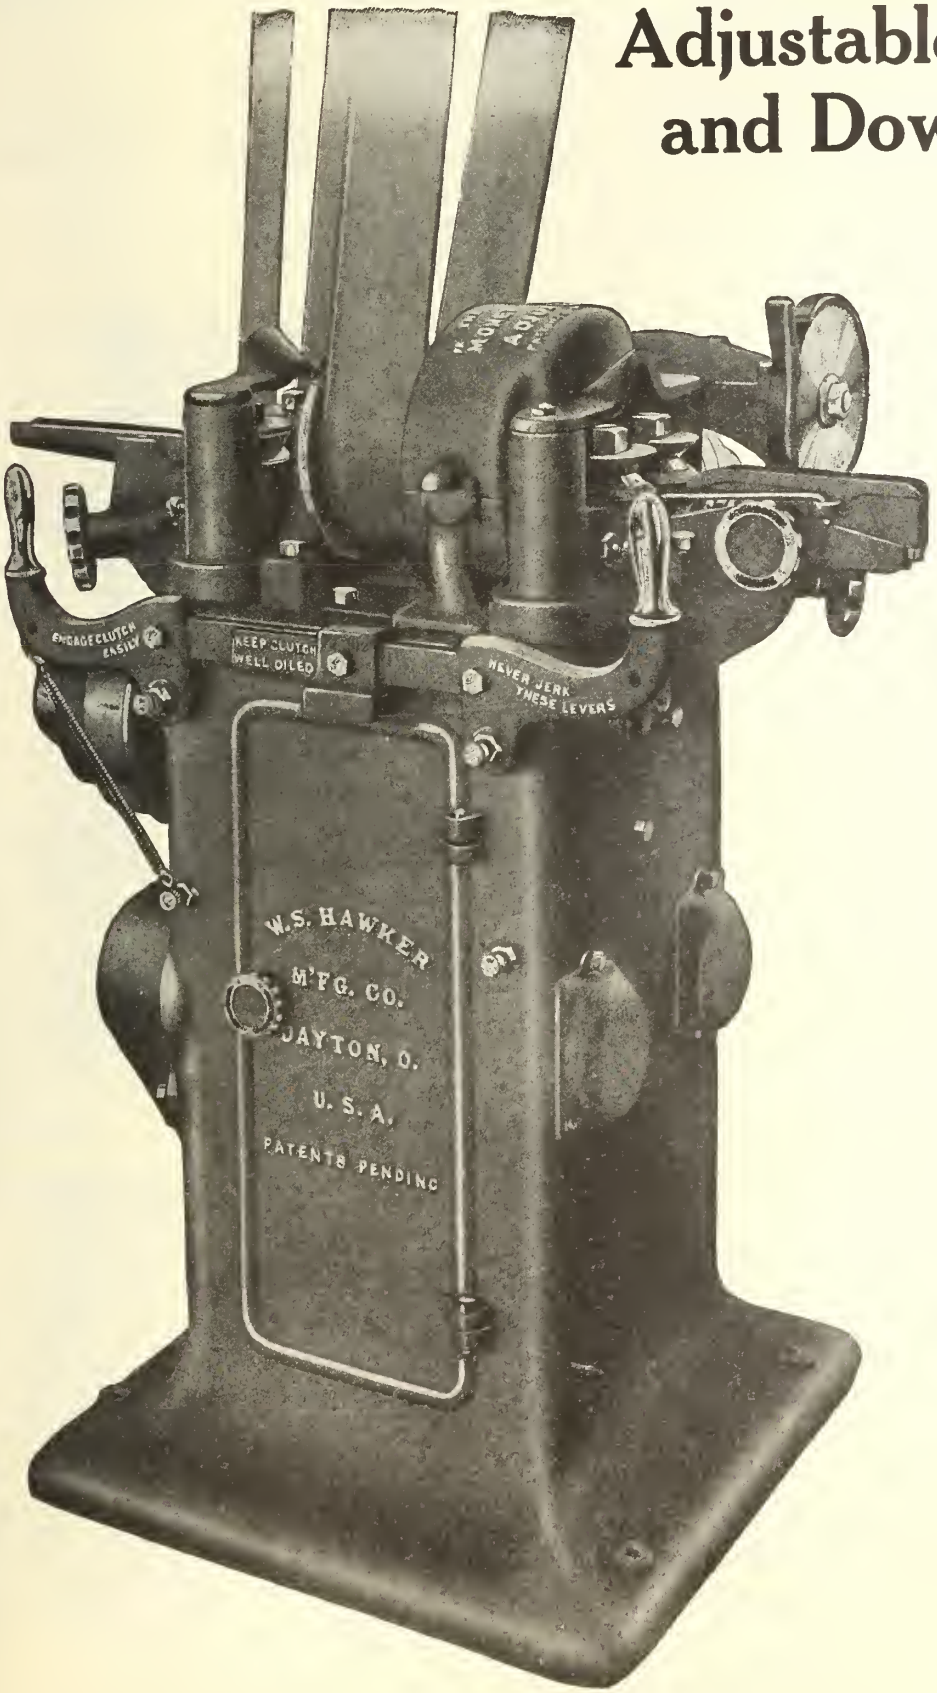
KNOBS The Period Knobs we placed on the market a few months ago are proving very popular. If you have not received samples ask for them now.

ROSETTES A new Period item to accompany the knobs.

Waddell Manufacturing Company

Coldbrook and Taylor, N. W. Grand Rapids, Mich.

The Money Maker— Adjustable Rod and Dowel Machine



Capacity 30,000 to 40,000 lineal ft. per ten hours on 7/8 or 15/16 mop or sweeper handle stock.
If you are using any dowel machine of less capacity, figure your daily losses in labor and business.
Write us what dowel sizes you turn, and whether hard or soft wood. Ask for our demonstration proposition to show you how to double your production of dowel stock at the same labor cost.

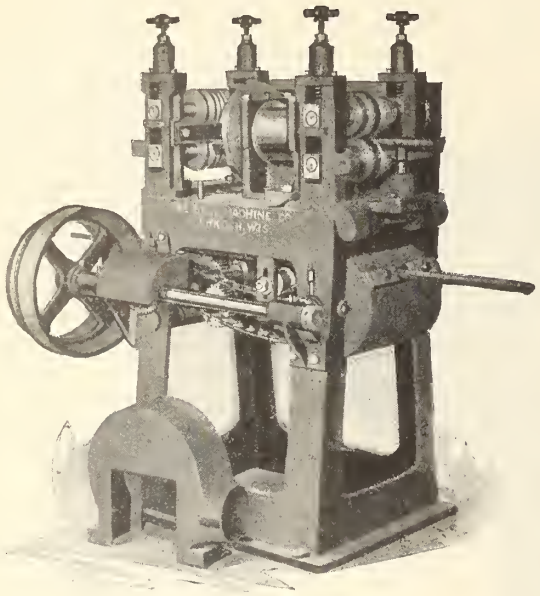
The machine that is sent under a guarantee to show you a gain of from 100 to 400 per cent before you buy it.
The improved dowel machine that 90 per cent of the largest and oldest machinery builders and dealers now endorse and recommend in preference to the solid chuck machines they themselves previously built.
One cutter head turns from ¼-in. to 2-in. diameter.
Turns hard or soft wood equally well.
Handles heavy, oversized squares.
No choking of the cutter head.
Smooth stock.
Accurate sizes.
Works stock as short as five inches.
Rolls automatically center variations in squares.
Machines built to turn from ⅛ to 6-in.
We want to hear from every user of a solid chuck dowel machine.
We can save you from one dollar out of every two, to four out of every five that the operation of solid chuck machines costs you.
Engagements for competitive test solicited.
Formal orders not solicited. All sales made after demonstration.

The only question is, are you willing to cut cost of your dowel turning to one-half or one-third of what it costs with any make of solid chuck machine?
Machine delivers the goods before you buy.
State conditions of stock closely
Special conditions require special equipment.

W. S. Hawker Mfg. Company, Dayton, Ohio

Make Your Own Dowels With the "BELL" Machines

The Fastest and Most Practical Equipment For the Purpose



Adjustable Rod and Dowel Machine

The fastest dowel machine in the world.

Constructed to withstand the heavy and constant strain to which this type of machine is subjected.

Equipped with a universal four-knife cutter head adjustable to turn rods of all diameters from ¼" to 2" in either plain, spiral groove, longitudinal groove, or imitation reed wind. Special machine for turning rods of larger size.

Cutter-head mandrel is mounted at each end in ball-bearings of the highest grade.

Out-going feed rolls have combination of grooves so that many sizes can be made without changing feed rolls. The in-going feed rolls are adjustable for all sizes of squares.

Will work stock as short as 4½ inches.

Furnished with countershaft or motor drive.

Dowel Cutting Off and Pointing Machine

This machine is for cutting off and pointing dowel pins from long rods.

It will cut and point dowel pins of all diameters up to ¾", and in any length up to 6 inches.

Capacity of this machine is from 300 to 400 pins a minute. Any boy can operate it.

All working parts are completely enclosed and thus protected from dust and dirt.

Absolutely no danger to operator.

The floor space required by this machine is only 22" x 36".

Tight and loose pulleys on machine.

Furnished with belt or motor drive.

Adirondack Garnet Rock

Garnet — indisputably the most efficient abrasive for hardwood sanding and finishing.

The Supremacy of Garnet

Garnet is not only sharp but hard enough to resist longer than any other abrasive the continuous wear on such woods as oak, walnut, birch, maple, etc. It has a real affinity for the vast majority of sanding operations, combining just the right degree of sharp cutting and lasting qualities.

Herman Behr discovered the superior qualities of crushed Garnet and first introduced it for work on wood and leather in 1879.

Since then his untiring efforts have given to the woodworking industries Garnet abrasive coated products that have gained and held the confidence of thousands of manufacturers.

Care and disregard of cost in the selection of only the best raw materials, scientific methods of manufacture, constant attention to details of refinement, and skilled workmen with decades of experience are the foundations of Behr Garnet Quality.

Fifty years as manufacturers of sandpapers to meet the exacting demands of direct consumers—the men most interested in whether the goods are high grade and economical—attest the universal approval of Behr Garnet abrasives.

To all those who *know* and *use* sandpaper, the name B E H R signifies the highest attainment in sandpaper manufacture.

41 DRY KILNS SOLD IN JULY

BOSTON, Aug. 14.—It is definitely reported that the B. F. Sturtevant Co. of Hyde Park, Boston, Mass. received orders for no less than 41 High Humidity Dry Kilns during the month of July. Some of these were repeat orders indicating the satisfaction these kilns have already given.

One went to the Argentine where unusual tropical woods will be successfully dried and seasoned. The ever-increasing use of Sturtevant Kilns all over the country is due to the wonderful results obtained.

Green lumber straight from the saw can be thoroughly dried ready for shipping in from 3 to 30 days. Some manufacturers put their lumber in this Kiln already cut to size because there is no warping, checking or end-splitting. Others use the Sturtevant Kiln for drying fine hardwoods because there is absolutely no case-hardening or honeycombing.

It is the rapid circulation of air of exactly the right temperature and humidity across both surfaces of every piece of lumber in the Kiln, that is responsible.

Recently a large electrical manufacturing concern found a quantity of quarter-sawn red oak on their hands that was badly case hardened and to all intents and purposes, useless.

Tests were carefully made which resulted in putting the whole of this case-hardened lumber in the High Humidity Dry Kiln. Practically every stick was recovered.

The Sturtevant Co. issue a comprehensive catalog dealing fully with the subject of lumber drying backed by government reports. If you write them for a copy of this catalogue, it will be sent you, free.

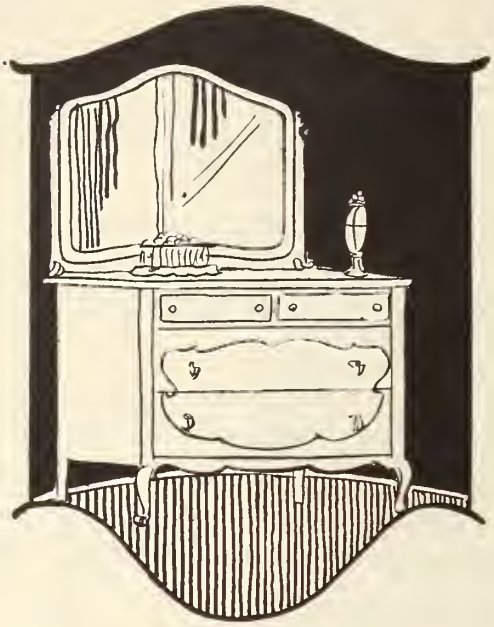
BARR-HOLADAY LUMBER CO.

BAND MILL AT LOUISE, MISS. GREENFIELD, OHIO

We cut Iowo grown walnut exclusively BOTH Lumber and Veneers



It Makes a Good Product BETTER

The quality of the lumber and the veneers in your product is an integral part of the quality of the product itself. Better lumber means better product—better prices—better sales.

Investigate IOWA Walnut—grown in the deep, rich loam of Iowa corn land it develops a strength and fineness no ordinary walnut can quite match. Cutting in our exclusive walnut mill by men who specialize on walnut brings out every inherent fineness of the native log. Let us demonstrate.

Write or Wire for full information and prices on your needs of walnut lumber and veneers before you buy.

Canadian E C & S *Birch*

A fine type of wood for Store Fixtures

Store fixtures are primarily for selling goods. Consequently too much emphasis cannot be placed upon their appearance.

Kent-McClain Limited, a Toronto firm of store fixture manufacturers with a reputation that extends across the Dominion believe in this theory and practice what they preach. In the photograph above, the store fixtures are made of Canadian Birch supplied by Edward Clark and Sons, Limited.

Canadian Birch, the premier hardwood is as beautiful in appearance as many of the costliest imported hardwods. Its texture is close and even. It lends itself admirably to the skill and artistry of the craftsman. And from the standpoint of the purchaser there is the real economy which the use of Birch always effects.

For your own benefit and that of your customers use more Birch. Any information you require will be gladly furnished by us. Let us quote you on a trial carload.

MAHOGANY

Rarely are such stores of precious wood to be found as may be seen in our yards. Across the seas from tropic lands it comes. From thick jungles where the light of day but dimly penetrates and where tangled native paths make difficult the bringing out of timber. Here the black man labors, risking life from jungle dangers, that supplies will not diminish and your orders may be filled.

Twelve million feet per year is the capacity of OTIS mills. An adequate supply is always on hand for prompt shipment. Get our prices.

It Is "Value Plus" That Counts

Andrew Carnegie is said to have once remarked: "It is the work I did in addition to the work I was expected to do that made me successful." The same thought is also expressed by Sheldon in his "Science of Business," where he used the words, "He profits most who serves best." It is the "value or service plus" when given by either employer or employee that counts.

This truth is not realized by the average employee who seems to give more thought to the clock and to putting-in the time than to seeing how much he can produce and thus rendering value plus for what he receives. When you find a workman who realizes the value of giving more than is expected, whose interest is in his work and the success of the organization of which he is a part, rather than in the weekly pay envelope, it will usually be found that his earnings are greater than those of his fellow employees and that he is the one who wins promotion and forges ahead rapidly. It is usually necessary to earn more before increased earnings can be expected and there are few employers who will fail to recognize and reward the man who shows the most in the way of results.

It is a poor rule that will not work both ways so that the employer must render "value plus" to those under him, before he can expect to profit most. There are those manufacturers who strive to give value plus to their customers in the way of value and service, but at the expense of the men who produce the goods. When competition is keen and orders scarce it is value that counts. Under such conditions it is easy to succumb to the temptation to make a slash in prices and then make up for the cut by reducing wages.

In addition to satisfying one's customers, all employers have a distinct duty to perform towards those in their employ. It is those employers who realize this and strive to put it into effect, who have the most to offer customers in the way of value and service. This "value plus" to be rendered the employee may take the form of good wages, satisfactory working conditions, interest in the welfare, improvement and advancement of all employees as well as in their home life and comforts, an incentive for high productiveness in the way of extra earnings, etc. This latter idea when developed along equitable, accurate lines has been found to be unusually effective in securing the good-will and co-operation of all employees, with gratifying and satisfactory results, Workmen cannot be forced to be efficient. It is only by an understanding of the hearts of men and of the natural laws of service that a nation, industry, firm or individual can hope to succeed .

* * *

Elsewhere in this issue will be found an article dealing with several methods of paying for labor, in which mention is made of the value of providing incentives for high productiveness. It might not be out of place to stress one point in this connection and that is the value and necessity of establishing such incentives upon a proper foundation. This is desirable from the viewpoint of both employer and employee. As far as the furniture manufacturing and other branches of the woodworking industry which produce a wide variety of lines are concerned, the ordinary forms of piece work, whether the rates are expressed in time or money, are of little use if the rates are based on past performance or upon the result of time studies that merely give times for certain operations on pieces of given dimensions. This is because of the wide variety of lines manufactured and the rapidity with which the designs are changed. Many of the rates so established would be of little value at the end of, say, six months, owing to the changes in the line which occur in that period, necessitating either further time study to set new rates or guessing at them. Further there is no assurance that rates based on past performance or upon straight time study are correct.

* * *

In other industries it has been found that a vast amount of comparative data, expressed in common terms, so that true comparisons can be made readily, is necessary for the establishment of rates that bear a fair relation to what the operation times should be, that are accurate and that are equitable to all concerned, and the same holds true in woodworking. Further, these rates should be so developed and charted that any production or cost clerk can quickly set accurate rates on new designs and new work without resorting to time study, or estimating or without considering past performance. It is here that basic time standards, as are known in woodworking, differ from ordinary piece work rates or time rates, for in addition to being based on comparative data gathered in different plants, they are so developed and expressed that rates for a wide range of sizes and shapes may be taken from one graph. Thus correct rates on new lines and unusual forms of work are readily ascertainable.

There is plenty of room for both employers and employees in this great woodworking industry to give "value plus." As this attitude becomes widespread those who belong to this class are not only going to get more pleasure from their day's work but they will also profit accordingly.

What Should be the Output of a Special Moulding Department?

A Study of the Operations of Mills Handling Special Orders Shows that, in Spite of Plant Efficiencies, Idle Time Seriously Cuts Down Production—Size of Runs is the Index to Net Yield

The delay occasioned by set-ups or knive changes is the factor that most seriously limits the production of special mouldings. When operators have also to grind their cutters, tail their machines and perform other duties connected with moulder operation, the output is bound to be still further restricted, but even where a special grinding department is maintained, leaving the machine men free to set up and feed, the actual running time is found to be but a comparatively small fraction of the total pay time. Thus an investigation, as detailed below, in the plant of one of the largest producers of special mouldings, shows that, in spite of an unusually efficient work plan, the average idle or lost time amounted to 52.2 per cent of the total pay time. This figure was obtained after a two-months' analysis of the production of ten moulders, so that the result is certainly a fair average of conditions as they pertain to the particular plant in which the study was made.

The problem of the special moulding department, therefore, is to increase the yield as much as possible, in spite of the necessity of incurring waste time through setting up, tailing the machines, grinding the cutters, etc. This may be accomplished to a certain measure by maintaining a separate grinding department and a crew of offbearers, and also by "bunching" items to decrease the number of set-ups and increase the size of runs. Of course, the use of straight-grained material and fast feeds tend to increase production, but if idle time is to be minimized, the size of runs must be made as large as possible.

To indicate what may be expected from moulders operating on special lines, the following record of the operation of a special moulding department will be of interest. The plant in question employs ten moulders and the observations were made over two periods of one month each, the total production for the two months exceeding 1,750,000 feet. The Millwork Cost Bureau was responsible for the study on which the following figures and comment are based.

The data for the two months is shown in the accompanying table. At the end of the first month, machine No. 11 replaced machine No. 2. No changes were made in operators.

The plant which maintains the moulding department under consideration is one of the largest manufacturers of special work. Due to "bunching" of items, its runs, as a whole, probably average more

11	141.0	24,093	40	5,530	2,930	34.6	602.3	2.8
	1,725.4	781,760	1,016	53,152	50,372	48.7	769.4	7.6

Summary—Two Months

Total time, 3,591.9 hours or	215,514	minutes
Total production	1,767,995	lin. ft.
Total set ups	2,272	
Running time	102,939	minutes
Idle time—includes setting up but no knife grinding	112,575	minutes
Loss	52.2	per cent
Average run per set up	778.1	lin. ft.
Average yield per minute of total time	8.2	lin. ft.

lineal feet to the set up than is common in most special mills. Moulding orders, as far as practicable, are allowed to accumulate so that the various items of one size and design may be run on the same set up. This firm also maintains a grinding department and a crew of offbearers; hence the moulder operators need not concern themselves with cutter grinding or tailing their machines. Set ups or knife changes, however, are performed by the operators.

Over 52 Per Cent Waste Time

In spite of this efficient work plan, the average idle or lost time occasioned through set ups, whetting up, oiling, and unavoidable delays amounted to 52.2 per cent of the total pay time. Converted to minutes of loss per single run, amounts to 49½ minutes. Where operators do their own knife grinding and tailing, and bunching of like items is not resorted to —other conditions being equal—the lost time will be higher and the yield per minute lower.

If the production of the entire department for the two months were based on only the **actual running time,** instead of total pay time, the yield would be 17.1 lineal feet per minute. That figure represents maximum or 100 per cent production and would be attained only if the whole quantity, 1,767,995 lineal feet, were put through the department in one run. One must conclude, therefore, that the millman who, even though he has not conducted tests of this sort, is nevertheless endowed with sufficient faith to proclaim to the world that his stickers produce 35 or 40, or even more feet of special moulding per minute of pay time—not running time—is laboring under a serious delusion.

The individual machine performances listed in this record reveal some significant facts; viz., the highest speed attained by any machine, considering **running time only,** was 39.6 lineal feet per minute—machine No. 1, second month. Machines Nos. 1, 3, 6 and 9, by reason of longer runs during the second month, show increased net yields. Machines Nos. 4, 7, 8 and 10, because of shorter runs during the second month all show decreased yields. It is interesting to note that machine No. 2, in the first month, while incurring through many set ups for runs little higher than the average, a high percentage of idle time, nevertheless, ranked second in production for the month. The conclusion must be that the production consisted of straight-grained woods which permitted using faster feeds. Just the reverse is true of machine No. 11—its output evidently was composed of "impossible" or cross-grained material. Machine No. 5, while not maintaining its production during the second month, did have longer runs, but apparently they were of more difficult lumber.

Straight-grained material and fast feeds make for high production, but the real index to net yield is "size of runs."

Production in Other Plants—Factory No. 2

Other investigations of a like nature have been carried out by the Millwork Cost Bureau, the data being tabulated below:

During a week's operation, involving 50 work hours per machine, 2 moulders employed in the production of special mouldings show results as follows:

	15" Moulder	10" Moulder
Total time, minutes.	3,000	3,000
Total run, lin. ft.	32,622	12,866
Total set ups.	112	65
D4S set ups.	40	6
Set ups of 100 lin. ft. or less	74	36
Set ups of 500 lin. ft. or more	14	6
Shortest run per set up, lin. ft.	8	15
Longest run per set up, lin. ft.	6,500	2,600
Average run per set up, lin. ft.	291.3	198.2
Average production per minute, lin. ft.	10.9	4.3

Converting the above to an average of both moulders will give:

	Both Moulders
Total time, minutes.	6,000
Total run, lin. ft.	45,508
Total set ups	177
D4S set ups	46
Set ups of 100 lin. ft. or less.	110
Set ups of 500 lin. ft. or more.	20
Shortest run per set up, lin. ft.	8
Longest run per set up, lin. ft.	6,500
Average run per set up, lin. ft.	257.1
Average production per minute, lin. ft.	7.6

The record of the 15" Moulder shows an unusually high number of set ups for the week. This is probably attributable to the fact that 40 of the 112 knife changes were for "Dressed 4 sides" material.

The rates for the average production per minute are based on the total number of working hours, including set ups, delays and all idle time.

Factory No. 3

During a week's operation, involving 54 work hours per machine, 2 moulders employed in the production of special mouldings show results as follows:

	No. 1 (10")	No. 2 (10")	Both
Total time, minutes.	3,240	3,240	6,480
Total run, lin. ft.	18,460	27,263	45,723
Total set ups.	83	48	131
Shortest run, lin. ft.	9	5	5
Longest run, lin. ft.	1,098	3,700	3,700
Average run, lin. ft.	222.4	568.0	349.0
Yield per minute, lin. ft.	5.7	8.4	7.1

Factory No. 4

During a period of 6 weeks, 2 moulders employed in the production of special mouldings show results as given below. No record was kept of the number of machine set ups, but there were no long runs. Most of the very short runs were made on machine No. 2.

	No. 1 (12")	No. 2 (8")	Both
Total time, hours	207.8	319.0	526.8
Total time, minutes.	12,468	19,140	31,608
Total run, lin. ft.	127,244	97,036	224,280
Yield per minute, lin. ft.	10.2	5.1	7.1

In both the above instances, the yields are based on the total number of working hours, including set ups, delays, and all idle time.

New Edition of Thomas' Register

The thirteenth annual edition of Thomas' Register of American Manufacturers has just been published. The new volume is 4,500 pages in size, is cloth bound, and while listing only the products and raw materials from United States sources of supply, is used by nearly 700 purchasing agents and buyers for Canadian concerns. The book is divided into three main sections. Over 300,000 makers of 70,000 articles or products are listed in the first section, there being, for example, 2,0166 kinds of machinery classified, with the names of the makers of each kind given. There are 99 kinds of acid classified, 285 kinds of brushes, 85 kinds of leather, 110 kinds of pins, 63 kinds of soap, 242 kinds of valves, 65 kinds of wax, etc. In another section all the manufacturers are listed alphabetically, with addresses of head and

branch offices, officers of the company, etc. An exclusive feature is the capital rating showing the size of each concern, giving the reader some knowledge as to whether the firm is a hundred million corporation or a small forty thousand factory with limited capacity. A third section lists 50,000 branded articles with the names and addresses of the makers of these trade named products. There is also a list of exporters and importers, with a directory of banks, commercial organizations and trade publications. The Thomas Publishing Company, New York, represented in Canada by the Canadian Buyers' Register Company, 91 Constance St., Toronto. The price of the book is $17.50 delivered in Canada.

How do You Pay for Your Labor?

Do You Make Use of an Incentive Plan of Wage Payment Based on a Definitely Established Standard of Production?—The Earned Time Plan, Through its Fairness and Basic Soundness, Creates Employee Confidence

By L. R. Wright*

A writer in a recent issue of a well-known trade journal stated that through the use of an incentive plan of wage payment, it is usually possible to secure worth-while increases in production, such increases varying anywhere from forty to ninety per cent. Whether or not his estimate of the resultant improvement is correct, it is generally conceded that paying for what is produced results in greater production and what is more, if the rates of payment are established upon a fair, accurate basis, the workmen, as a rule, prefer to work under some form of an incentive plan.

The trouble in the past, and even today, is that when an attempt is made to establish a rate by which to pay for what is produced, an accurate, definite basis upon which to establish such rates is lacking, with the result that the rate is more or less guessed at or estimated. If under these conditions, the workmen earn more than it is thought they should, the rate is cut. This process is often continued, with the result that the workmen decide that they are not going to be permitted to earn much more than the regular day wage, and relax their efforts. This is unfortunate, for not only has the confidence of the employees been lost but the highest degree of productiveness possible under this method of payment has not been attained.

An Accurate Standard Must be Established

The trouble was that a definite basis for fixing such rates is lacking. Establishing rates upon a basis of past performance or upon straight time study work in one plant is not satisfactory, because when that is done, the basis upon which the rates are fixed is invariably not correct. The average time in which a certain operation has been performed is, for example, ten minutes, whereas the actual time in which that operation should have been performed is seven minutes. Any rates fixed on the basis of the past performance time of ten minutes are bound to be too high. This holds true ninety-nine times out of a hundred, for it is seldom that an operation is performed as it should be.

In establishing the price to be paid for certain work either in money or time, the workmen have a pretty good idea as to whether or not they were guessed at or as to whether or not they are fair. This point must be considered. For this reason, it does not do to adopt the attitude that because this operation requires ten minutes under present conditions a rate based on five minutes would be about proper. For general, all around satisfaction, the operators must know, must be shown, if necessary, that the basis upon which the rates are fixed is both definite and accurate. You should be able to say, for example, "here is a rate based on standards established by studies made in a number of plants. This work can be turned out in seven minutes but we are willing to pay at the rate of eight minutes for all you produce." In other words, on a definitely established standard of production, it is possible for the average operator to earn a bonus of fifteen per cent over and above his regular wage.

The idea of payment in time has been for the past number of years, considered much better than rates expressed in dollars and cents. Under the ordinary piece work plan, the men were paid so much money per unit of production. This is not at all flexible, inasmuch as the amount of money paid must be raised or lowered to confirm to the general level of wages. This means that the rates must be changed frequently. Again such a method does not permit graduating the rates so that an employee who had been with the organization for a number of years could be rewarded for length of service, dependability and punctuality, as a new employee would expect the same rate per piece as the rest receive. When a rate of so much time per unit of production has been established, a permanent basis for paying for performance has been established. If a certain operation can be performed in ten minutes today, then regardless of any changes in wage levels, it should not take any longer the next year or the year after. True the ten minutes may be paid for at the rate of fifty cents an hour one year and forty cents the next, but the time rate would not change. Further, if the men on a certain class of work are receiving fifty cents an hour, a new employee can be paid at the rate of forty five cents an hour, based on the same time rates, until he makes good, when his pay can be increased to the same as the rest are receiving. This gives him an added incentive to stay and make good.

Success of the Earned Time Plan

This time rate plan of wage payment, or earned time plan, is being worked very successfully in different woodworking and furniture plants. The time rates are best estimated upon basic time standards, allowing a definite incentive for high productiveness. These standards indicate operation times as they should be, without any reference to what they are, and thus provide a definite, accurate basis upon which to intelligently fix rates. Using basic time standards in this way, the operation time is brought down to as near the standard as conditions permit before the time rates, including the incentive, are established.

The Productive Power of Good Lighting

Plant Managers Should Recognize the Importance of Daylight in Their Factories —Output Is Increased, Greater Accuracy and Better Workmanship Are Obtained and Labor Turnover is Lessened

By Russell J. Waldo

Business leaders are fast coming to realize that light plays an important part in controlling the production of their plants. Ever since man has used shelter for the making of any product, he has been accustomed to carry his work from a dark spot to the window where he might work with greater rapidity and more accuracy. It has within the last few years been proved that to have the maximum production, the room must be lighted sufficient to permit

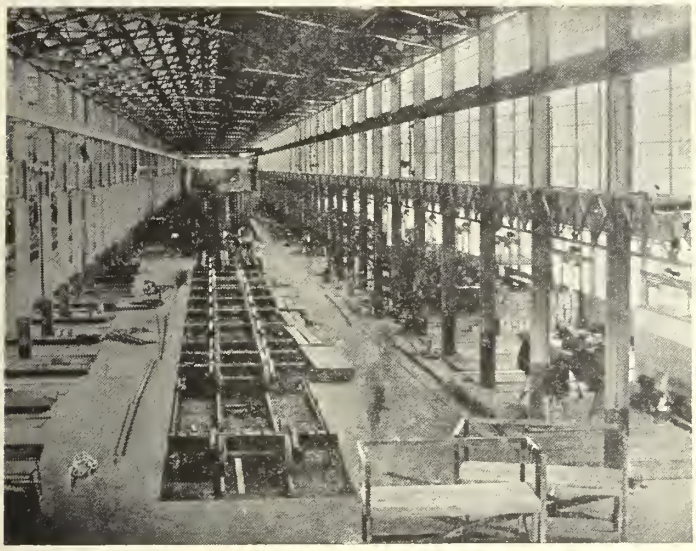

Fig. 1 An even distribution of light is obtained from window walls

the worker to work at his best and with little detraction or extra work in search of light.

There are various methods of lighting the plant during the day—window walls, saw tooth roofs, white paint, and in extreme cases artificial lighting. While every plant has need for proper artificial lighting, it is the purpose of this article to deal only with natural light requirements, leaving artificial lighting to be discussed in a separate article.

It is only through satisfactory illumination, and that preferably by daylight, that employers can obtain maximum efficiency from their workers for it is light that controls to a very large extent an employee's output, contentedness, safety and workmanship. Furthermore, properly lighted plants have greater and better production because of the ease which is possible in checking up the work by both workers and inspectors.

In considering the question of proper light, it must be recognized that glare is as bad as insufficient light. This is overcome by shades or by whitewashing the glass, preferably by the first method, because the shades can be lifted in case of darkening clouds.

Some of the Advantages of Good Lighting

One of the most important considerations in connection with the proper lighting of plants is the safety element. If the proper lighting is provided to protect the worker and allow him to see thoroughly before he acts, he is then in a position to produce more. Dark corners, passageways and poorly-lighted rooms contribute to bodily injuries. An employee may fall in a dark spot or he may become injured because the work-room is dark. Therefore, the proper amount of light by protecting the worker from injury, will contribute very materially to his efficiency.

Sufficient light permits the greatest accuracy in the employee's workmanship. No workman can do his work well when he must strain his eyes, which he must do if lighting is poor. Proper lighting will allow him to exercise care and accuracy in his work with the result that the workmanship will be of the best. In this manner the scrap pile will be decreased and there is less waste because poor lighting will cause the workman to misjudge or miscalculate his measurements, which means scrap every time. Because he can readily see what he is doing his productive ability is increased to its maximum. He is not required to spend time in determining whether he is right or not. Therefore, it is possible to work with greater rapidity.

Proper lighting is one of the most potent factors in improving working conditions. No employee likes to work in a poorly lighted plant for it deadens his

Fig. 2 Good workmanship is a natural result of good lighting

ability and has a tendency to make him melancholy. It is a well-known fact that the man who works in the well-lighted building feels better and puts more snap into his work. He can work with greater accuracy and is not under that strain which comes when a man feels that he might be wrong on account of the poor light.

Cleanliness in the Plant

Proper lighting tends to increase order and neatness in the workroom. Because things are visible dirt does not accumulate and scraps, such as boxes and

papers, are not thrown about as they are in a dark room. Men are able to keep their machines and work benches cleaner and to take a greater personal interest in their work-place. Cleanliness and neatness of this kind help to make the workmen feel more contented and more comfortable than they do in a place littered up with papers and boxes. Incidentally, this has been found to decrease labor turnover very materially.

Another result of proper lighting is the fact that there is better supervision of the men. In a well-lighted room the men may be more easily controlled, while the darkened room encourages soldiering, and often a nap during the work hours. In the well-lighted plants the foreman is able to see in all parts of the room which would be an impossibility in a poorly lighted plant.

It is of vital importance that natural light should be obtained from every available source during the daylight hours. This is not only important from a human standpoint but from the productive standpoint, and with the methods in use to-day for distributing light to the plants it is easily and cheaply obtained.

The three major considerations in proper daylighting are sufficient lighting area, continuous lighting, and proper distribution of the light. The first is obtained by using the greatest amount of window space. Continuous lighting is obtained by installing sufficient windows so that the greatest amount of light may be had even on the dark days. Proper distribution is obtained by properly distributed windows and in addition light walls to reflect the light down upon the work.

Figure 1 shows a plant interior with window walls. This is a striking example of what light can

Fig. 3 An installation of shades to control the light intensity

be obtained from window walls. The light is even and from the entire side of the building.

In Figure 2 we find the workers before the windows with sufficient light. Many plants have the work benches before the windows and the machines setting back. This is a good idea providing the entire wall is taken up with windows as is the case in the plant illustrated.

In plants having window walls the shade plays an important part. On sides exposed to the sun these shades are used as shown in Figure 3. This is a typical shaded room and proves very satisfactory in cases of close work.

The saw tooth roof deserves careful consideration both from the light and ventilating standpoint. In Figure 4 is shown the saw tooth roof of one large

Fig. 4 The saw tooth roof which contributes to even light and good ventilation

p'ant. When these sash face the north a very even light enters and makes the workroom uniformly light.

Plant managers are fast turning to their plant lighting in an effort to settle their production problems and rightly they should, for in the best lighted plants today are found the best work and the most efficient workmen.

Properties of a Good Preservative

A list of the various substances that have been used or suggested for preserving timber from decay would include a surprisingly large proportion of those known to industrial chemistry. By-products for which no use could be found have often taken their last stand as possible preservatives of wood. There have been sent to the U. S. Forest Products Laboratory for testing of their preservative qualities the condensed fumes of smelters, the waste liquors of pulp plants, the refuse of tanneries, the skimmed milk of creameries, and a wide assortment of compounds under trade names.

Very few materials have been found to have value as wood preservatives. Most of them lack one or more of the following requirements.

To preserve wood against decay a substance must first of all be poisonous to wood-destroying fungi. Decay in wood is not due to direct chemical action or action of the elements but is always the result of the activity of these plants which feed on the wood and thus destroy it. To prevent fungus infection, the preservative must be able to penetrate the wood thoroughly enough to form a continuous exterior shell of poisonous treated wood deeper than any surface checks which are likely to develop, and to retain its toxicity, or poisoning power, under service conditions.

Safety in handling and use is another important consideration. A wood preservative must not be a dangerous poison to men and animals, a highly inflammable substance, nor a material injurious to wood. If it seriously corrodes iron, steel, or brass

its use is limited because of its action on the treating equipment and on bolts and metal fastenings in contact with the wood in service. Color, odor, and effect on paint are sometimes of considerable importance.

Provided a preservative meets these requirements its cost, availability, and uniformity will largely determine its usefulness.

There are materials of established protective value now on the market which are both cheap and plentiful. The standard wood preservatives in the United States art zinc chloride and coal-tar creosote. Their value has been established by many years' use of millions of railroad ties, poles, posts, paving blocks, mine timbers, and other wood treated with them. Search for new and better preservatives is constantly being made, but in the meantime the wood preserving industry has at its command these reliable materials.

Are Your Men "Sold" on Safety?

The Workers Must First Be Thoroughly Imbued with the Importance of Safety Measures before Results Will Be Forthcoming

By J. M. Hatch*

To get the best results from safety measures requires first of all salesmanship, and the best results will be obtained only by salesmen who can get the viewpoint of the workers. Workers do not take kindly to one who does not know as much about their machines as they do themselves. So, in order to get the workers interested, let them make the suggestions as to how to guard the machines by just leading them up to the point. Guards made from their own suggestions will be the ones you will get results from. Do not make the men use your guards before allowing them to make suggestions, for what you have may work all right on some jobs and hinder production on others. The men should be the ones from whom to get the real facts.

It is just as important to use different methods with men, as to use different guards on the different machines, so one that is a good judge of human nature will get the best results—will prove the best safety salesman.

A guard should not be used as an ornament. Unless it is practical you had best throw it away, for if the men think it is there just to give a shop a well guarded appearance rather than to get real results—the interest and value are lost.

At the American Seating Company we have employee representation and are thus able to give the men a voice in the matter of safety. We have a safety committee from the House of Representatives and one from the Senate that go through the factory each month and investigate and get suggestions from the men. Then only do the committees take action by submitting reports at the next meetings of their bodies. Tags with numbers are left on the parts of machines found dangerous by the committees and are not removed until they are corrected by the safety engineer who turns in the tag. By this method the committees can keep up with conditions in all departments.

*Foreman, the American Seating Co., Grand Rapids, Mich., before the Woodworking Section of the eleventh annual National Safety Congress, Detroit, Mich.

But to return to the specific question of salesmanship, selling safety to operators of woodworking machines. To accomplish this various methods may be employed but we have found the first aid, contests between departments and the employees' magazine as the biggest contributing factors.

Take the first aid, which was established in 1921, and let's make some comparisons. In 1920 the total number of days lost due to accident was 1,346. In 1921, with the first aid in operation, this figure was reduced to 377. I might be able with a little figuring to tell you what this has meant in dollars and cents to the company and in dollars and cents to the workers, but suffice it to say that the compensation paid out in 1920 was $6,914.41, while in 1921 it was but $1,317.28, a saving of $5,597.13 here.

Again, that bugbear—infection—was made the subject of a vigorous campaign to have minor injuries treated in the first aid and our records show that the lost time due to infection was reduced from 349 days in 1920 to 13 days in 1921.

In one department in our plant the accidents were reduced from an average of 52 a month to none at all for the twelve consecutive months ending March 31 last.

Needless to say, safety devices alone did not accomplish all this. It required the co-operation of every man in the department and this in turn meant that every man in the department was first "sold" on the value and importance of safety—a feat which could not have been engineered had not the management been more than passively interested in the subject.

H. M. Taliaferro, our manager, was one of the handful of men who early came to a realization that industry had become a slaughter house and set about to make a study of safety on the theory that accidents were not unavoidable. He was one of the organizers of the Safety Council in Grand Rapids, just as he was among the first to see that in industry the human element had been overlooked in the mad rush for mechanical development.

And as Mr. Taliaferro said to us in the beginning: "Strange as it may seem, the hardest thing will be to get the man on the job to see the point." He insisted a man's dependents had a right to expect to see him return whole to them after his day's work and that we must "sell" him first of all on the importance of self-protection.

So the industrial relations department started its wheels in motion, always keeping this objective in mind and in the case of the department cited the same committees, co-operating with the men and the safety engineer, adopted safety devices, many of them invented by the men, while a contest between departments was started on the basis of time lost monthly.

But this was not all. The first aid was at work, in which the full-time nurse played an important part in obtaining the co-operation of the men while "The Seater," our plant paper, was getting the message across through news stories, illustrations and editorials, and at the same time building up goodwill in the organization, which makes that valuable asset—the goodwill of the customer—possible.

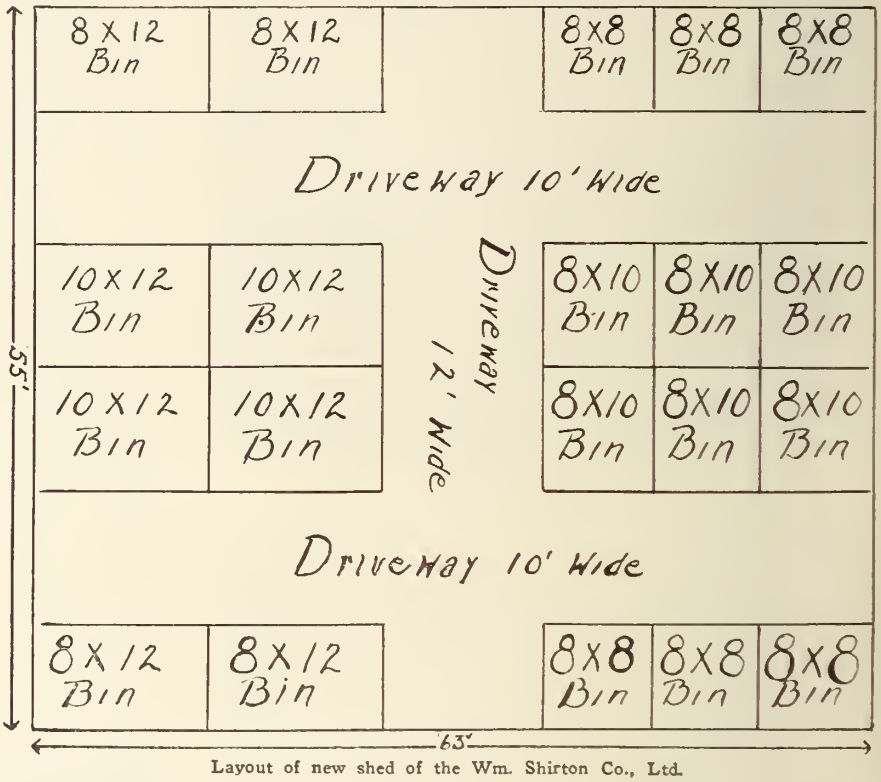
And before closing, here's another big little point: See that the foreman is thoroughly sold on safety before spending money and effort on a safety campaign. He is the one closest to the men.

New Storage Shed for End Piling Lumber

Progressive Ontario Woodworking Plant Completes Shed Where Space is Saved by End Piling—Care Must be Exercised in Piling the Narrow Stock to Obtain Substantial Piles

The William Shirton Co. Limited, of Dunnville, Ont., which is one of the most progressive retail lumber and woodworking plants in Southwestern Ontario, has just completed a spacious new lumber storage shed. The structure embodies the latest features and provides for the end piling of all lumber. K. J. Shirton, who is head of the company and also vice-president of the Ontario Retail Dealers' Association, says he will be pleased to have visits from any retailers who may be interested in building a structure of similar design.

The accompanying view affords an idea of the exterior appearance of the shed while the floor plan shows the size and location of the bins and driveways. The foundation of the building, which in dimensions is 55 feet wide, 63 feet long and 18 feet to eaves, is of concrete 10 inches in width and extends 12 inches above ground level. The floor also is concrete 4 inches in thickness. The walls are sheeted and covered with corrugated iron. The frame was constructed in bents on the ground and then raised in a manner similar to the method pursued in building a timbered barn.



Layout of new shed of the Wm. Shirton Co., Ltd.

The roof storage shed is covered with asbestos roofing on top of cedar sheathing. In the centre three rows of cement piers support the posts of the building and the bins are divided by 2 x 6 inch studs covered with sheeting on one side.

Mr. Shirton says the building was constructed for the end piling of lumber. This method results in saving a great deal of space but care must be exercised in piling, particularly with narrow width material. It is necessary to give strips, flooring and other narrow stock more of a slant or incline than wider lumber, otherwise the piles will have a tendency to topple sideways.

The shed will hold from 125,000 to 150,000 feet of material. Rough lumber for milling is piled on one side of the structure nearest to their factory, and dressed material on the other. Mr. Shirton states they have already found the building to be a great convenience enabling them to carry a large stock of lumber ready for customers and also assisting to keep a close check on all quantities of dressed material.

The approximate cost of the new storage shed was $3,000. Mr. Shirton says they were able to save a little by using a certain amout of unsaleable material such as their short hardwood sheeting and culls from 2-inch hemlock. In using this stock more work was required; therefore, the cost was not reduced to any considerable amount, but it is always some advantage, he declares, to clean up a yard occasionally of cull material which is bound to accumulate.

New dressed lumber shed of the Wm. Shirton Co., Dunnville, Ontario

The business of the William Shir-

ton Co. was established in 1895 and conducted by Mr. Shirton, the founder, until 1909 in which year he passed away. A partnership was then formed of the family and carried on as such until 1915 when a change was made to a joint stock organization under the present name.

The company use hydro-electric power but at one time employed chiefly natural gas. This, however, is becoming exhausted in that district, but Mr. Shirton says it would be more economical than either electricty or steam providing its continuity and abundance were assured.

For many years, the company have manufactured cross-arms which developed into quite a prominent side line. In the making of cross-arms B. C. fir is employed as this wood is, the firm declare, the most desirable from every point of view. The dimensions generally in use are 3 x 4 finished and 3¼ x 4¼ finished, while the lengths vary from 4 to 10 feet. Mr. Shirton added that, if manufacturing cross-arms exclusively, they could supply the demand for the whole of the Dominion. Many Western mills are now making cross-arms which are also turned out by other firms in Quebec and in Ontario. The demand in Canada is thus pretty well taken care of. So far as an export trade for them is concerned, the excessive cost of transportation prohibits any large business being developed.

On Circulation Depends Kiln Drying Success

Inverted V or Chimney in the Centre of the Pile Helps in Some Degree but Other Provision Must be Made for Directing and Controlling the Flow of Air to Avoid the Production of Dead Air Pockets

By M. O. Reid*

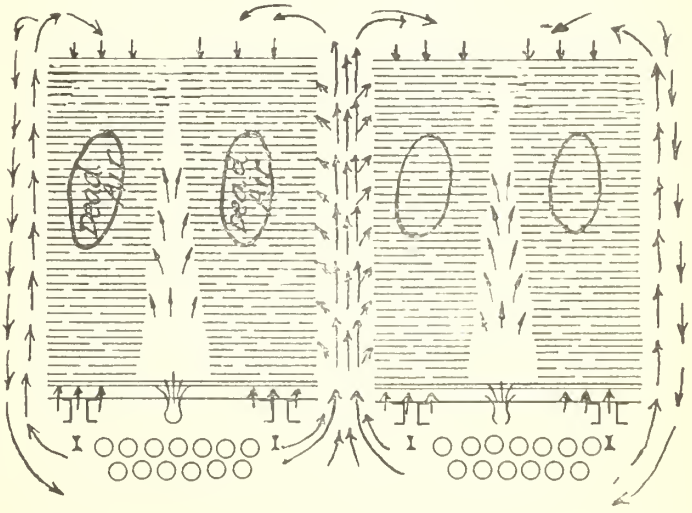
The article in the September "Canadian Woodworker and Furniture Manufacturer" by A. M. Smith entitled "Dry Kiln Capacity Increased by an Improved System of Piling" touches on a phase of dry kiln operation that is extremely important, that of securing a circulation of warm, conditioned air through the lumber piles. The necessity for even, adequate circulation has been treated so often that there should not be any need for emphasizing this phase of kiln drying, but there is plenty of room for a discussion as to how a good circulation may be secured.

In the average kiln, the circulation is what is termed "natural circulation." This term is used in contradistinction to circulation accelerated and maintained by mechanical means, such as condensers, water or steam sprays and suction or blower fans. In one, advantage is taken of the natural movement of heated air while in the other the warm air is literally forced through the kiln with a positiveness and speed not usually encountered except where mechanical circulation is used.

The natural movement of warm air is upward. As this air cools, it gradually drops so that in a room or kiln having a heating coil near the floor, there is a natural circulation of air up from the coil and down around the cooler walls and then up through the coil again. It is on this principle that most dry kilns are based. Provision is made for placing the heating coils near the bottom of the kiln and the lumber to [illegible] is placed above the heaters in the direct path of the upwad currents of warm air. The assumption was that the air worked up through the lumber, out of the top of the piles and down the sides again or in some out through ventilation placed along the ceiling or walls.

In developing this idea two important facts were overlooked. First, that while the movement of warm air is upward, there is also a strong tendency for the air to follow the line of least resistance, which means that in this case the warm air would rise around the lumber piles rather than work its way through them. The other point that was overlooked was as warm air picks up moisture, it gives up some of its heat in exchange for that moisture, becoming cooler and heavier and exhibiting a strong tendency to fall or descend. For this reason, the circulation through a pile of damp lumber is downward rather than upward.

Building the piles of lumber with an inverted V or chimney in the centre as suggested in Mr. Smith's article, helps some, as it tends to carry some of the warm air into the heart of the piles. This actually divides the dead air space, which so often exists in the centre of a pile, but unless other provisions are made for directing and controlling the flow of air, dead air pockets will develop in either leg of the V. For this reason lumber piled this way should dry a



little more quickly than in the more solid piles but merely making a chimney in the pile has very little effect on the circulation. Perhaps this is best illustrated by the accompanying sketch. The arrows indicate how the air would move and the dead air pockets which would form are also shown.

Depending upon the natural movement of warm air only, or even when aided by ventilators and air ducts, it is extremely difficult to secure an adequate circulation through the centre of the piles of lumber unless the air movement is controlled and directed along certain definite channels, preferable along the

*Associate Engineer, Forest Products Engineering Co., Chicago.

lines the air currents would follow if not checked or obstructed. They would naturally move upward from the heating coils outside the piles, downward through the piles and thence on down to the exhaust ducts and heating coils. Where the air movement is sluggish or uncertain the drying is slow and the conditions are more or less beyond control. Before the rate of drying in the sluggish spots can be increased and brought into conformity with the rate at which the rest of the pile is drying, the circulation must be made uniform throughout the pile. When this is accomplished, the drying period may be materially shortened and the cost of drying reduced for it is no longer necessary to hold the stock in the kiln while waiting for the slower sections to be brought down to the desired moisture content. Thus, without making any changes in operation methods, or in the temperature and humidities carried, a considerable reduction in the drying time can often be effected simply by improving the circulation in the kilns.

Working along these lines, it is often possible to effect a marked improvement in the working of a kiln through simple and inexpensive improvements in design and equipment tending to facilitate the circulation through the tiers of lumber, by directing the warm air through the piles and providing definite channels of travel.

What is Involved in Burden or Overhead?

Its Meaning is Not Always Clearly Understood and Consequently Serious Errors Develop in Cost Estimates—The Factors Involved in Burden and How they are Distributed in a Woodworking Plant

By U. E. Germain*

On considering the different articles published in recent issues of the "Canadian Woodworker" on the cost of production in woodworking factories, it occurs to me that while the direct cost of production is very well understood the overhead or burden is not clear to some manufacturers, and is wrongly applied in their cost estimates. This is misleading and more harmful than having no cost record at all, as it leads to erroneous figures which only spell disaster.

The matter of computing and distributing the burden or overload, which constitutes quite a large percentage of the total cost of the finished product, depending on the conditions under which it is manufactured, is one of the most puzzling problems involved in costs. At the outset it must be understood that burden has to do with the productive cost of the goods, and not with the marketing of the goods. Selling or marketing costs do not enter into burden of production at all. Factory costs, which is what we wish to discuss, is the value of the product when it is turned into the warehouse—the selling expense must not be included in the factory cost figures until the products are in the warehouse or ready to market, as otherwise it would inflate the actual value of the goods.

In burden is included every expense necessary to the manufacture of an article outside of the direct labor cost and cost of raw material. The different elements which make up burden are as follows:

1. Administration.
2. Indirect labor,
3. Power. lighting, heating,
4. Insurance, taxes,
5. Depreciation, repairs and maintenance.
6. Interest on borrowed money and general bank charges.

Determination of the Burden Factors

Administration or management of the factory is a burden to the extent to which the time of the manager, his assistants, the office staff, the finance department and other units is involved in the productive end. As an example, if the manager of the factory looks after the selling, and his assistants look after the manufacturing end, at least a fraction of the salary of the manager goes into selling expense. The same principle applies to the finance department, the pay roll department, etc., as will be explained later.

The indirect labor includes all the men and boys about the factory who do not work directly on the produce. The superintendent's salary comes under this classification; likewise that of his assistants and foremen.

The power, lighting and heating burden is determined from the cost of same and distribution prorata to the floor space of the factory, or the horse power used by each department. The latter way is far better as the manufacturing of some lines may need large floor space but little power or vice-versa. The distribution can be ascertained from the horse power of the machines used.

The insurance burden is distributed according to the value of the investment in each department and is treated separately in the cost. The same applies to taxes.

The repairs and maintenance burden is generally kept separate, and it is easy to find the accurate figures for each department. The hard nut to crack is the depreciation of plant item. which is so pliable a matter that no accurate figures can be depended upon. Depreciation applies both to the machinery and the building. We will not enter into this point at length but let us remember that depreciation has to be studied very carefully and the local conditions considered. The depreciation of the plant will depend upon the nature of the building, a wooden frame building absorbing a greater percentage of depreciation than a concrete or brick building. The rate of depreciation on buildings varies from 2 per cent. to 8 per cent. according to the stability of the building and the nature of the work that goes on within. In the case of machinery, the depreciation is considered from two different standpoints of great importance—the efficiency of the machine with regard to its production, and its daily capacity as compared with other recent machines. A machine may be in perfect order and do very good work, but its capacity is limited and not up to that of newer machines, and thus it is not as efficient and its percentage written off should be larger than in the case of another machine which does not cut down the speed of production. Besides, there is also the depreciation

*Of U. E. Germain Lumber Co., Montreal, P.Q.

of wear and tear, figured accordingly to the nature of the work of the machine.

The interest burden can be figured either in the cost of production or with the sales cost. It is established that borrowed money is often required on account of slow collections on the sales, and the cost of same should be figured in the sales cost . This is a matter to be decided by the manufacturer himself.

Distribution of Burden

Now that the different elements which make up burden or overhead have been discussed, let us study how they are distributed over the production of the factory and absorbed in the initial cost of the product. This is the important point in determining the cost of the product when delivered to the warehouse or to the shipping room.

As a sash and door factory is generally only a part of a general lumber business, carrying on a retail trade, a planing mill and hardwood flooring business, besides a general line of building supplies, it is necessary that the total burden or overhead should be distributed first amongst these departments in accordance with their importance and the amount of time and capital involved in each department. To illustrate further we will say that our total burden for one year is $27,982.00 and is distributed as follows: wholesale and jointing department, $8,750.00; retail and building supply department $5,340.00; planing mill moulding and hardwood flooring department $4,300.00; and factory department $9,592.00. We have to do with this amount of $9,592.00 as our general burden for the year, which is divided into twelve equal amounts to apportionate the burden per month, and we find an amount of $799.33 per month. The indirect labor burden is then figured every month, as it changes according to the amount of non-productive help about the plant. Suppose we find this item as follows.

Superintendent	$300.00
Foreman	160.00
Non-prod. labor	430.00
	$890.00

which brings up our total burden for the month to $1,689.33. This is the amount which has to be borne by every operation in the plant and which goes to make the cost of production.

While there are many systems and ways to distribute this amount to each operation, my experience has proved—that the only efficient plan of distribution of burden is by the productive hour method, which means that every minute of a workman's time is carrying a percentage of burden, together with his wages. The percentage is worked from month to month according to the total of productive hours during the previous month, as shown on the pay roll.

We find that we have a total number of productive hours for one month of 4,400. Our total burden is $1,689.33. The amount of burden per hour would then be .384 cents for every productive man in the factory. Thus a benchman earning 48 cents per hour is really costing .864 cents per hour.

This, on the surface, looks very accurate, but still a further consideration of distribution is to be undertaken. As all the men in a factory are not working on the same wages and doing the same kind of work, the rate of overhead per hour cannot be the same for all. For instance, a benchman cannot be assessed as high as an operator of a high priced machine, for the reason that the benchman only uses heat and light, while the machine is using power, light and heat, besides which the machine he operates is carrying a large part of burden and depreciation. Burden is thus re-distributed according to the importance of the operator under consideration. The total monthly burden, however must not be exceeded or underestimated. This is easily arrived at with little practice. The changes in a factory are not very numerous, and the whole thing will right itself quickly with a little observation. The cost card on a certain job would then look something like this:

Lumber W.P. 45 feet at 85	$3.69
32% of waste	1.18
Hardware (Store Order No. XXX)	.87
Time card	
Per cent. of overhead 15 min. at40	.10
Machine operator 30 minutes at 65	.325
Breaker up, 15 minutes at .55	.138
Percent of overhead 30 min. at 45	.225
Bench operator 3 hours at 40	1.20
Percent of overhead 3 hours at 20	.60
Cost of production	$8.328

Then there is the cost of selling, handling, carting, delivery, collection, advertising, etc., to be reckoned with, but we will not discuss them here for they can be ascertained from your daily experience.

These few remarks are made from actual experience in the application of costs in a large woodworking factory and while they are not complete they will demonstrate one easy way of distributing burden in a sash and door factory which is a bugbear to many millmen.

Copper Salts Improve Casein Glue

It has been found that copper salts added to casein glues greatly increase their resistance to moisture and also make them more durable when exposed to the action of molds and fungi. Casein glues containing copper are nearly as moisture resistant as blood albumin glues.

In the preparation of copper-casein glue at the Forest Products Laboratory, 2 to 3 parts by weight of copper chloride or copper sulphate are dissolved in about 30 parts of water and are added to every 500 parts of the ordinary casein, lime, and water glass glue. The copper solution is poured into the glue in a thin stream. The violet-colored lumps formed at first by the coagulation of the glue by the copper solution are reduced by stirring vigorously for about 15 minutes, and a smooth violet-colored glue results. It is necessary to add the copper salts after the other ingredients are thoroughly mixed, in order to obtain beneficial results. Copper added to the casein before the lime and water glass is ineffective.

Glues containing little lime are especially improved by the addition of copper. A low-lime glue with copper may be as resistant to moisture as a glue with more lime in it, and copper does not shorten the "life" or period of workability of the glue as much as more lime would.

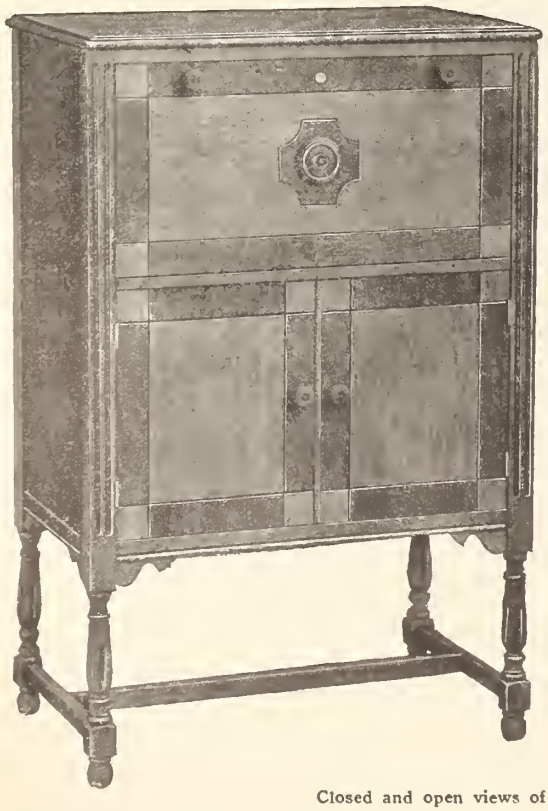
To get sense out of anything you must put some into it.

There is one advantage electricity has over all other powers; it can be taken and used in any odd corner at a very low cost.

Capitalize the Radio Craze!

Furniture Manufacturers Should Take Advantage of the Popularity of the Wireless Telephone by Marketing Cabinets for Radio Outfits—A Demand for High Class Cases

The growing popularity of radio can be made to work out to the benefit of furniture manufacturers and cabinet makers through the manufacture of radio cases; in fact several firms on the other side of the line have already seen the possibilities of good business in cabinets of this kind, and the suggestion seems to have an appeal to firms in Canada who are fitted for the handling of such business. A few months ago when the radio craze began to take the country by storm the apparatus was in many cases of a temporary and make-shift nature. However, so well developed has the science become within the last few months that the apparatus is now of a highly developed type—often quite intricate and expensive. In keeping with the development which has taken place in the design of the radio equipment itself, there has also been noted a tendency to improve the cases or cabinets in which such apparatus may be housed. In some instances radio apparatus has been installed in phonograph cases while, of course, the simpler equipment has been fitted with comparatively inexpensive boxes or cabinets. However, the wireless enthusiast, who has purchased or made a high-class set is no longer content with a cheap case for his apparatus. He wants a cabinet entirely in keeping with the class of apparatus he possesses, and for that reason there is now a growing demand for well-finished, high-class cabinets that will not only be adequate protection for the delicate radio machinery but will also be ornamental furniture for the home. Indeed the radio has become such a piece of home equipment that it behooves furniture manufacturers and cabinet makers to recognize the probable permanence of its popularity and to take advantage of the possibility of making it as handsome a piece of furniture as the phonograph has become in recent years. For that reason a little ingenuity can easily be exercised in the design of cabinets suited to radio requirements. These can be made as fancy and finely finished as the demand warrants; indeed it may reasonably be supposed that with the high quality of the radio equipment now being marketed, there will be a very keen demand for cases of the finest quality and workmanship. Just to indicate what may be done along this line we are showing two illustrations of a cabinet recently put on the market by the Maddox Table Co., of Jamestown, N.Y. The illustrations show a particularly handsome cabinet, both closed and open. In commenting on this particular design, the Maddox people say, "The development of radio has opened a new and rich field of profit for furniture manufacturers and dealers. Every radio set requires a cabinet." The design shown is made in oak, mahogany and walnut, waxed finish, two-tone. A sliding shelf admits of easy access to the rear of the apparatus. The upper section will house any type of radio apparatus and the lower space is ample for batteries, storage, etc. The cabinet measures 29 x 17½ in. in plan and 46 in. in height.



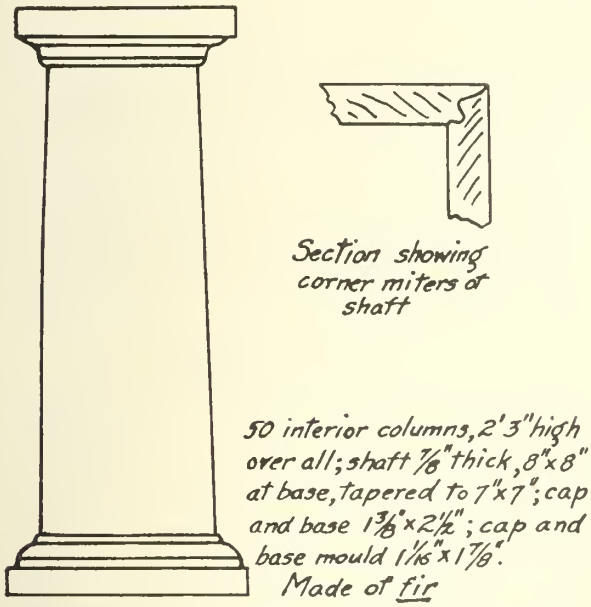
Closed and open views of a radio cabinet by the Maddox Table Co.

A Difference in Costs of 122 Per Cent

Why Should the Estimate of the Cost, Without Profit, of Fifty Columns Range Between $135 and $300?—How Can You Meet Competition Unless Estimating is More Intelligent?

The subject of the cost study this month is a job involving 50 interior columns, 2 ft. 3 in. high over all, 8 in. x 8 in. at the base, tapered to 7 in. x 7 in. at the top. The shaft is 7/8 in. thick and the cap and base 1 3/8 in. x 2½ in. The material is assumed to be fir. A number of millmen have submitted figures representing their respective ideas as to the true cost, without profit, of producing this order. These figures, which are tabulated below, certainly show some surprising features and admirably serve to emphasize the lessons which this series of articles is intended to point out.

The "Canadian Woodworker" feels that a great many millmen have no idea and do not know how to form an idea of what their costs are. We feel further that this is a situation that demands a serious attempt toward securing a remedy. The woodworking industry is no longer a hit and miss proposition. It is a well-established business that should be run on scientifically determined lines. The day has passed when a mill operator should determine whether he has made money only by analyzing his bank account at the end of the year. He should know from day to



Section showing corner miters at shaft
50 interior columns, 2'3" high over all; shaft 7/8" thick, 8"x8" at base, tapered to 7"x7"; cap and base 1 3/8"x2½"; cap and base mould 1 1/16"x1 7/8". Made of fir

The figures in the next column tell how costs are guessed at

day and on every operation whether he is running at a profit or a loss. It may be necessary under certain circumstances for him to run at a loss but, at least, he should know that he is doing so and that he is not under any misconception about the amount of money he is losing. Some operators are in the habit of running along month after month under the impression that a healthy surplus is accruing to their credit when, as a matter of fact, upon sizing up the business at the end of the year, they are surprised to find a loss that more or less seriously injures their business. We are all in the business to make money—not exorbitant profits or profits based on "putting something over," but at least a legitimate return for capital invested and labor expended. But a profit can only be determined if we sell our products at a price above what our outlay was in making them; in other words if our selling price exceeds our cost. This pre-

No.	Material	Waste	Bench hrs.	Rate	Machine hrs.	Rate	Commercial Burden	Total
1	$60.00	20%	25	$.90	25	$1.20	20%	$135.00
1a	64.35	10%	55	.75	15	1.50	25%	160.10
2	39.97	20%	50	.88	62	1.04	15%	170.72
3	60.00	15%	40	.95	50	1.25	15%	184.50
4	115.80	20%	30	1.00	12	1.50	20%	196.55
5	72.00	20%	60	.90	40	1.30	15%	197.80
6	52.47	10%	50	.85	50	1.50	20%	203.97
7	54.21	20%	47	1.00	61½	1.17	20%	207.80
8	58.20	15%	54	1.00	70	1.20	20%	235.44
9	55.80	20%	125	.85	40	1.07	20%	245.84
10	40.74	7%	100	.60	100	1.50	20%	300.89

supposes, of course, that we know our cost, but this seems to be the bugbear if we are to judge by the figures that have been published month by month in these articles.

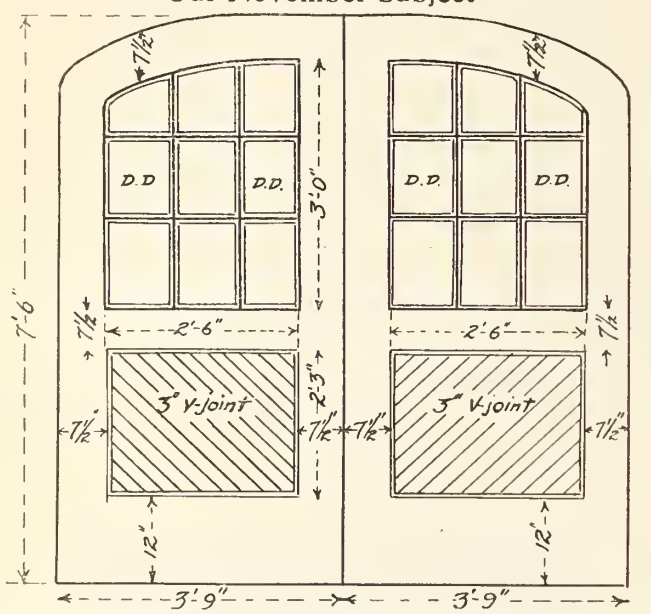
The wide disparity in many of the quotations naturally leads us to suppose that there has been some error in calculating the true cost. Making all due allowances for differences in conditions in different plants, there is no justifiable reason for the wide variance that is generally shown in connection with these cost studies. In practically every instance there are one or two firms who have estimated either extremely low and extremely high, while there are usually several who match up within close limits. It is probable that those whose figures come pretty close to the average are the ones whose estimates of cost are reasonably correct while it is almost safe to assume that the extremes are away out in their estimating.

This situation is just what all of us in the woodworking industry would like to improve, and the "Canadian Woodworker" has felt that one way of ultimately securing a better basis of costing is to throw a little light on conditions as they are. For this reason we have suggested certain jobs month by month and have obtained cost estimates from a number of mills that are qualified to handle the orders concerned. There is no thought of running down or belittling those estimators whose figures do not show any similarity to the average, but rather is it the object to use those figures only to point out the moral which we want to emphasize—that there is need for some improvement in costing methods if the woodworking industry is to be placed on the plane which its importance justifies and if woodworkers are to be able to make legitimate profits from their operations. In this policy we have been commended in letter after letter; in fact we are constantly being thanked for offering these comparative studies and thereby drawing the attention of some firms to the need of some improve-

ment in their system of estimating their costs.

In the particular study which has been selected for this month, a range of 122% in the total estimated cost of the job is evident—a percentage that is all too high if these estimates are based on a definite knowledge of cost data. In the individual factors which are involved in the estimate there is even more flagrant variation. Take material, for example. The estimates range all the way from $39.97 to $115.80 for the material required for these 50 columns. We admit that the estimator furnishing the low figure does not specify the amount of material necessary for the job, and so we cannot determine if he has made any error in taking off his quantities. That is a possibility, of course, for previous studies have shown that millmen, as a whole, need some instruction in quantity taking. The other estimates show practically the same amount of material in each case, the proportion of waste, however, varying from 7 to 20%, the latter figure being the more prevalent. The firm whose estimate was high, $115.80, put the price of the material at 50% above anybody else, which accounts for the unusually high figure.

Our November Subject



Readers are requested to submit their ideas of the cost of this pair of garage doors for the November issue. The doors are 2 in. thick and made of white pine.

On the question of labor the figures tell an interesting story. With bench hours running from 25 to 125 and machine hours from 12 to 100 there is surely something in error, especially when the firm that estimates a small amount of bench labor also estimates a small amount of machine labor. Quite frequently it is possible that one firm's estimate will show an unusually high amount of bench labor, but it should show a corresponding decrease in machine labor or vice versa. The rates charged for labor are fairly uniform, bench labor rates at from $.60 to $1.00 and machine labor at from $1.04 to $1.50. These figures are, of course, supposed to include burden which is one of the most difficult things to determine in woodworking operations. The importance of the proper establishment of burden rates is well emphasized in Bigelow's new book on "Management in the Woodworking Industry," in which he states: "One of the first steps in establishing cost is to work out the ratio of burden to the direct labor charges for the various departments of the business. This is to provide the mechanism for making a charge each month to the account representing work in process, to cover the burden applicable to the cost of the product, in proportion to the amount of direct labor incurred during the month." In this connection it may be interesting to point out that the Millwork Cost Bureau has just compiled returns from its members and determined a new burden rate based on conditions as they are at present. Up till now the average burden of the 500 members of the Bureau has been 57 cents per hour for machine help and 34 cents for bench labor, whereas now these figures are respectively 64 and 38 cents.

The Millwork Cost Bureau has made an estimate of the cost of the job shown in this month's study and their figures are given below for the sake of comparison.

Material				
Including 20% waste				$ 54.21
Machine Labor				
Ripping and Cutting	7	hours		
Planing (Pony)	8	hours		
Shaping	26.5	hours		
Belt Sanding	20	hours		
	61.5	hours	@ $1.17	71.96
Bench Labor				
	47	hours	@ $1.00	47.00
				$173.17
Commercial Burden 20%				34.63
Total Cost				$207.80

As several letters have asked us to continue this series, we shall take another job for November and ask our readers to submit their estimates of the cost at an early opportunity. The subject for study is comparatively simple but it is such a job as might be handled in almost any mill—a pair of garage doors of the design shown in the accompanying sketch. Will you not please submit an estimate for the sake of more accurate costs in the woodworking industry?

Varnish Hints

A brush mark or flaw in the first coat, unless removed, will show in the last coat no matter how many coats are applied. Each coat of material on top of a rough mark makes it more difficult to remove.

The durability of finishing materials increases, up to a certain point, with the number of coats applied. The priming coat is supposed to exclude moisture from the material underneath it, and form a receptive surface for subsequent coats. Hence it dries more quickly and harder than other coats.

How do You Pay for Your Labor?

(Continued from page 54)

In this way, maximum production is secured, for the rates are based on definitely-known, minimum operating times.

When the workmen are convinced of the stability of the rates and also of their fairness, they usually put their shoulders to the wheel and work with a will and spirit of co-operation seldom, if ever, found where a definite incentive is lacking. The result is a gratifying increase in production and, as a consequence, lower costs.

Is White Oak or Douglas Fir Best for Barrels?

After Making Comparative Tests the Forest Products Laboratory Draws Several Conclusions Respecting the Merits of the Two Woods —How Fir Staves Should Be Manufactured

Comparative tests of white oak and Douglas fir barrels are described in a recent issued report of the Forest Products Laboratory, Madison, Wis. This report outlines at some length the comparative merits of containers made of these two woods in the light of the results of a number of experiments carried out under the jurisdiction of the Laboratory, the various tests to which the barrels were subjected and the reactions that were obtained in the various processes being described and illustrated in considerable detail.

The barrels used in the tests are described as follows: The oak barrels were furnished by the St. Louis Cooperage Company, St. Louis, Missouri, and consisted of 48 barrels divided into six groups of eight barrels each; group No. 1, 5/8-inch stock, 6 hoops,; group No. 2, 5/8-inch stock, 8 hoops; group No. 3, 3/4-inch stock, 6 hoops; group No. 4, 3/4-inch stock, 8 hoops; group No. 5, 7/8-inch stock, 8 hoops. The barrels were made from quarter-sawed white oak. The material was practically straight grained and free from defects. The barrels were of excellent workmanship and were well coated with paraffin on the inside. The staves varied in width from about 2½ inches to about 7 inches. The heads were usually composed of four pieces, though two heads each were composed of three pieces. The pieces of the heads were joined together with 5/16-inch hickory dowels. The Douglas fir barrels were furnisted by the Western Cooperage Company, of Portland, Oregon, and consisted of thirty-three barrels divided into three groups of eleven barrels each which that company in their forwarding letter, described in the following terms: "The stock in these packages is sawn from No. 1 Douglas fir timber and represents our No. 1 grade 3/4-inch oil staves and our No. 1 grade 20-7/16-inch heading in 3/4 and15/16-inch thickness. There are to be thirty-three barrels forwarded to Madison, eleven of which will be hooped with six hoops and headed with 3/4-inch head; eleven more hooped with eight hoops and headed with 3/4-inch heads, and the balance to be hooped with eight hoops and headed with 15/16-inch heads. All heading used in these packages have glued joints, and the packages were set up from average stock the same as received from our mill, there being no special selecting."

The barrels, in each case, after being filled with water, were subjected to the following tests: Side compression, diagonal compression, internal pressure, side drop, and diagonal drop. Charts were used to plot the progress of each test, and voluminous memoranda notes taken of the various points of strength and weakness developed by the containers while under the different treatments applied. A mass of valuable data was secured which should prove of incalculable value to both manufacturers and consumers in determining the relative value of white oak and Douglas fir as cooperage stock. The following notes are taken from the summary as it appears in the report:

Oak Barrels

In each kind of test the first water to appear on the outside of the barrel was usually from the seepage through the pores of the wood at the chime. The first leak usually occurred either between the staves and the head or between the staves at the chime. In all the tests except the internal pressure the first leak was usually coincident with the slipping of the staves.

In the internal-pressure test there were two general classes of failures: (1) By springing and breaking of the head; and (2) by leaking between the staves at the bilge.

In the diagonal-compression test the failure was a general failure of the head combined with the slipping of the staves. In the compression-perpendicular test the failure was a general leaking at the heads and slipping of the staves followed by the breaking of the staves at the bilge.

In the side-drop test the slipping of the staves caused loosening of the hoops and leakage at the heads. This was followed by breaking of the staves at the bilge. In three of the six tests the failure of the barrels was due to the heads being broken or forced out by the pressure produced by the impact.

The lower heads of all barrels tested by dropping on the chime were broken or forced out by the pressure due to the impact.

Douglas Fir Barrels

First leakage in nearly all tests was in one of two ways: (1) water passing completely around the edge of the head and appearing on the outside of the barrel in the angle between the head and the chime or projecting end of the stave: (2) water passing partially around the edge of the head and thence though the pores and appearing as small drops on the edge of the chime. Leakage of the first type is described as "leakage at croze," and the second as "seepage through chime." There were very few instances in which there was leakage between the staves except after the barrel had been quite severely deformed as in the side and diagonal-compression tests. In the diagonal-compression tests leakage due to crushing of the edge of the head occurred at a fairly early stage. As a special test barrel No. 13 was so placed that the end grain of the head came at the point of pressure, and, leakage did not occur until later.

Aside from the first leakage, types of failures differed, of course, with the kind of test.

In side and diagonal-compression later failures were by slipping in stave joints and shear or splitting of staves, combined with opening of the joint between staves and head with splitting of head.

In this test there were numerous instances in which staves split or sheared their entire length. In fact, it seemed to be almost as easy for this to occur as for staves to slip on each other at the joints. This applies also to side and diagonal drop tests.

Final failure in side drop and in diagonal drop tests was the driving out of the head by the shock of the contents.

Final failure in internal pressure tests was by breaking or bursting out of the heads.

At first leak in side compression, the Douglas fir barrels take only about two-thirds of the load carried by the white oak barrels. The white oak barrels, however, begin leaking at a much smaller deformation than do the Douglas fir, and the product of load and deflection at first leak is in every case of comparison higher for Douglas fir than for white oak. These facts indicate that when subjected to shocks against the bilge, the Douglas fir barrels, although they develop less force before leakage, yield much more (or farther) and can absorb fully as great a shock as the white oak. It should be noted in this connection that a common practice is to store or stow barrels on their sides with the bottom row blocked at the quarters and upper rows laid in the "cantlines," or space between barrels of the row below and with the bilges above the heads of the row next below. It is to be expected that barrels arranged in this manner will sustain considerably larger loads than are found in the side compression test.

At first leak in diagonal compression, Douglas fir barrels take less load than white oak barrles. Here again, however, white oak barrels stand much less deformation than the Douglas fir, with the result that shock-resistance as indicated by product of load by deflection is practically equal for barrels of the two species.

The Douglas fir barrels average about three-fourths as high as the white oak in drop (both side and diagonal) at first leak. Approximately the same ratio applies to drop to produce leakage at the rate of one pound of water per minute.

When subjected to internal water pressure the Douglas fir barrels develop two or three times as great pressure at first leak as do the white oak barrels. The pressure required to produce leakage at the rate of 1 pound of water per minute averages about 30 per cent higher for Douglas fir than for white oak.

Conclusions

The following conclusions apply only to white oak and Douglas fir barrels and in the combinations of number, quality and dimensions of hoops and thickness of staves and heads as used in the tests described herein.

1. In the oak barrels, increase in thickness of stave is of much less value than increase in head thickness, and it is to be expected that oak barrels with 5/8-inch staves and 7/8-inch heads will prove fully as serviceable under many conditions as barrels with 7/8-inch staves and heads.

2. In Douglas fir, barrels with 15/16-inch heads and 3/4-inch staves are superior in resistance to internal pressure to barrels with 3/4-inch heads and staves.

3. When there is little change in moisture content, as in these tests, the eight-hoop barrels show but little superiority over six-hoop. When barrels are subjected alternately to moist and dry conditions and the consequent tendencies to swell and shrink, it is to be expected that the advantage of the eight-hoop barrels will be enhanced.

4. When barrels of both species are well and carefully made of properly-selected stock they compare as follows:

Douglas fir barrels have about two-thirds as great resistance as do white oak barrels to leakage under steady loads as in the bottom of storage piles. However, Douglas fir barrels probably have sufficient resistance to carry safely such loads as are likely to come on them in storage or shipment. The Douglas fir barrels, moreover, possess the ability to be deformed to a greater extent without leakage than the white oak. Resistance to shock is proportional to the product of load and deformation, and the Douglas fir and white oak barrels are practically equal in this product, indicating that when loaded on end in railway cars they may be expected to withstand equal switching shocks without leaking. After leakage has begun the steady force and the shock required to cause increased leakage is greater for white oak than for Douglas fir barrels.

When dropped upon the chime or upon the bilge, the Douglas fir barrels withstand without leakage about 25 per cent lower drops than white oak; indicating somewhat greater susceptibility to damage from rough handling in rolling or sliding down skids.

The Douglas fir barrels withstand from two to three times as much internal pressure before leaking as do the white oak barrels.

5. The Douglas fir barrels tested were made with 17 gauge by 1¾-inch and 18 gauge by 1½-inch hoops in order to have them like the oak barrels tested and to comply with I.C.C. specification No. 10. As Douglas fir is softer and exerts less force in swelling than oak, it is not certain that these sizes are necessary. Further tests would be required to determine the safe and most economical size of hoops for Douglas fir barrels.

Tests Were Made With Barrels of Best Quality

In connection with these comparisons of the white oak and Douglas fir barrels it is to be remembered that all barrels tested were of selected stock and well manufactured. The oak staves and heading were white oak, which is much more resistant than red oak to penetration by liquids. Because of this quality and because of other properties, such as greater stability of form and shape under changing moisture conditions, and greater resistance to decay, white oak, when clear of sapwood is recognized as much superior to red oak for barrel making. The Douglas fir barrels were from timber selected because of its special suitability for barrel manufacture. These points are mentioned to bring out the fact that the barrels tested were such as can be made only through careful attention to selection of timber and to manufacturing details, and that the white oak and Douglas fir barrels tested were of corresponding quality.

The results of these tests lead to the conclusion that with carefully-selected timber and carefully-manufactured barrels, white oak will excel Douglas fir barrels in serviceability under ordinary shipping conditions. However, white oak barrels, if of indifferently selected stock containing sapwood or defects, or if carelessly manufactured, may be expected to be much less serviceable than Douglas fir barrels well made of properly-selected material.

Selection of Timber and Handling of Stock

The selection of timber and handling of stock is carried out with great care by the larger manufacturers of Douglas fir barrels, and it is desired to call attention here to a number of points bearing on the making of barrels of the best quality from the species. These points have been developed from the experience of manufacturers, observation of the barrel tests described herein, mechanical tests of Douglas fir,

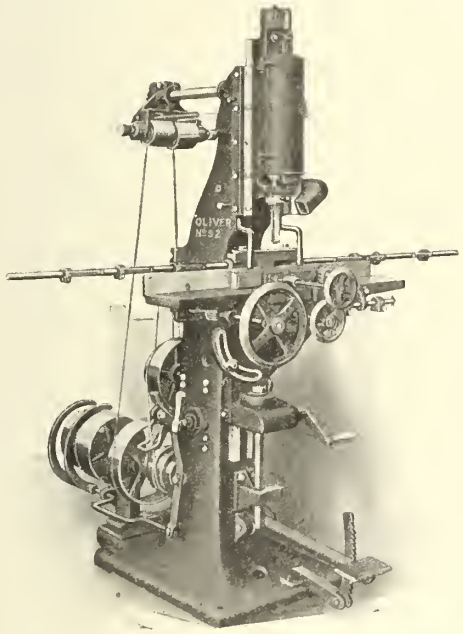
Machinery & Equipment

A New Power Feed Hollow Chisel Mortiser

A new power feed hollow chisel mortiser, known as the "Oliver No. 92," has recently been put on the market by the Oliver Machinery Co., Grand Rapids, Mich. This new equipment is designed to meet the demand for greater production than is possible with foot-feeding machines, and is particularly useful in factories engaged in multiple quantity manufacture of cabinets, furniture, sash and similar woodwork. A number of advantages are claimed by the manufacturers who especially draw attention to its flexibility, convenience, dependability, economy and compactness. Chisels from ¼ inch to 3/4 inch square can be handled and the stroke is adjustable from 2½ to 4 inches long. Stock 6 inches wide can be centred beneath the chisel.



The "Oliver No. 92" power feed mortiser"

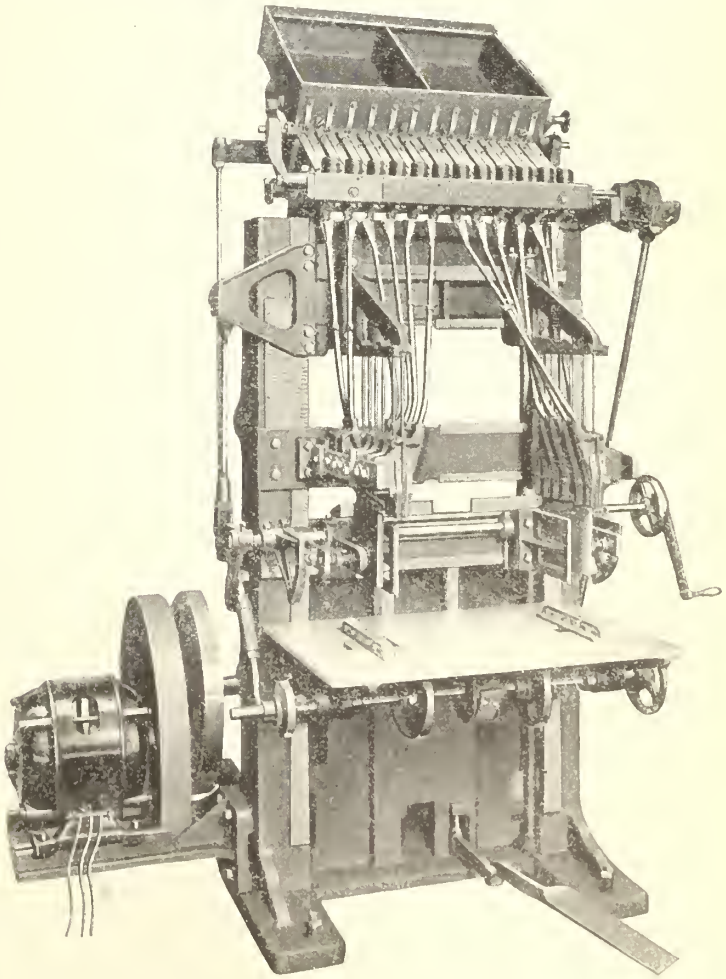
The mechanical construction of the machine is of the latest design, with the column enclosing the power feed mechanism with the exception of the drive pulleys. A built-in fan blower back of the column furnishes a constant air blast which cools the tools and keeps the work free from chips.

The power feed mechanism is extremely simple, being controlled by the foot lever and brought into action by a belt tightener which when released brings a brake into action on the rim of the drive pulley. A ratchet is provided to hold the lever down for continuous feeding. The power feed has three rates of feet, 18, 26 and 36 strokes per minute, by means of cone pulleys and a feed belt shifter. By throwing out the ratchet the continuous feed mechanism may be instantly stopped and the machine operated by single strokes. A universal combined table with screw clamp for 6-inch wide stock and hand wheel, rack and pinion for longitudinal travel, gauged by adjustable stops, is regularly furnished.

The machine may be obtained and fitted for belt or motor drive. In the latter case the usual drive consists of locating a 3 h.p., 1,200 r.p.m. motor on a bracket in place of the tight and loose pulleys, and coupling same to the drive shaft which carries the pulleys to the spindle, the fan and the power feed mechanism. Where 2 or 3 phase, 220 or 440 volt, 60 cycle current is available a motor-on-arbor type of machine may be employed. In this the countershaft and idle pulleys are eliminated entirely and the machine is driven by two motors, one a 1½ h.p., 3,000 r.p.m. motor directly on the spindle, and the other a 1 h.p., 1,200 r.p.m. motor direct connected to the cone pulley which operates the power feed mechanism.

Double End Box Nailing Machine

Something new in the way of a box nailing machine has recently been brought out by the P. B. Yates Machine Co., Limited, Hamilton, Ont. This is a double end box nailer which will nail a box together in three strokes with the exception of the lid,



New nailing machine manufactured by P. B. Yates Machine Co., Ltd.

providing it is end-nailed, that is, that the sides and bottom are nailed to the end pieces. The side can be nailed to the two ends in one operation, as the sides are nailed to the ends of the box simultaneously. The machine's capacity is limited only by the skill of the operator.

Another feature of the machine is that it can be arranged to nail combinations, such as four nails on the bottom and sides at each end, or four nails in each side and six in the bottom at each end. This variation in the nailing makes it adaptable for nailing boxes which are shallow in comparison with the width. Specially designed clamps for holding the ends of the box while being nailed also effectively straighten warped or crooked stock and align these pieces with the ends and the side. These clamps open and close automatically.

The machine can be driven by direct-connected motor or by belt. It is designed for box makers who end-nail their boxes and especially for nailing together apple boxes, pear boxes, butter boxes and the regular types of boxes used in the canning trade.

The accompanying cut represents the new double end box nailing machine, this particular one being the No. 12 A.B. machine, the number of the machine designating the number of nails that can be driven at one time.

Is White Oak or Douglas Fir Best for Barrels?

(Concluded from page 66)

and field observations of its properties and peculiarities:

1. It is believed by barrel manufacturers that material of suitable character can be secured only from trees grown in low-lying regions or so-called fog belts.

2. Staves of the Douglas fir barrels tested had an average of about 23 annual growth rings per inch. The minimum number was 7 and the maximum 44. It would probably be well to require that staves should have not less than 8 growth rings per inch.

3. It is recommended that Douglas fir bolts be converted into staves and kiln-dried as soon as cut from the logs, in order to avoid the rather rapid deterioration that may occur through the checking of short bolts in drying.

4. It is of prime importance to have staves as nearly as possible perfectly quarter-sawed or edge-grained. Incipient ring shake or weakness of bond between the annual rings is a type of defect rather frequently found in Douglas fir. Where this occurs in a stave having the annual rings at angle of less than about 60 degrees with its surface, slippage along the rings having such weakness is very likely to happen. It is recommended that in specifications for tight barrels of Douglas fir a limit be set to the deviation from perfect edge grain. The following is suggested as a simple and practical statement of the deviation:

"Staves must be so manufactured that the annual rings at any point do not deviate a line perpendicular to the face of the stave by more than one-half of the thickness of the stave."

The cutting of staves in this manner has a further advantage, since the shrinkage of quarter-sawn stock averages from one-half to two-thirds as great as that of slash grain material. For this reason barrels made of quarter-sawed staves shrink and swell less with change in atmospheric and moisture conditions and give less trouble with leakage. This is true of all species. The tendency to shrink and swell as well as strength properties are factors to be considered in comparing the suitability of various species for tight cooperage. The shrinkage or swelling of quarter-sawn stock with a given change of moisture content is practically the same for oak and Douglas fir. Consequently, it is to be expected that troubles with shrinkage and swelling will be least for the barrels whose staves are most perfectly quarter-sawed.

Why so Few Apprentices in Planing Mills?

Editor, Canadian Woodworker:—

I appreciate the interest you are taking in the apprentice question but think that there have been some misconceptions as to the progress we have made regarding this matter.

It has been discussed in a rather offhand way at two of our meetings, without any apparent solution having been offered. I will confess to being very much interested in this problem, but do not pose to be an authority on its solution by any means. There are several reasons why our boys are not interested in the planing mill business, some of which can be remedied by ourselves and some cannot.

In the first place, our industry has been one which has about as many failures to its credit as any line of business I could mention, and those of us who have survived, have done so by practicing strictest economy. We have paid ridiculously low wages to our mechanics, and a boy who is looking around for something to make his life work, has invariably passed us up, and can you blame him? This can be remedied by our charging a price for our products which will enable us to pay a decent wage, and make working conditions more agreeable thereby making the woodworking mechanic proud of his occupation.

A man is not going to learn a trade unless he feels assured that the remuneration he will receive will allow him to provide a comfortable living for himself and family. It is all very well for some of our visionary individuals to talk "guild," but in order to make it attractive, a prospective student must see a decent living ahead. We are bringing up our boys to live differently than they did a generation or so ago. I am a firm believer however, in preparatory school training, but you must have subjects to train. Many of our boys have a desire to be in the white collar class. This condition in my estimation will right itself in time.

Another reason why the workman does not take more interest in his work and encourage his boys to follow in his footsteps, is the curse of unionism, which we have had to contend with. If a boy in starting out, tries to make a record for himself as the the quality and quantity of the work he is turning out, he is invariably called where unionism reigns.

These things which I have mentioned, are only some of the problems we will have to solve before making any great stride toward encouraging our boys to become planing mill mechanics. I might say however, that we have in our employ, three or four boys who seem to be working out fairly well, which is rather encouraging.

C. E. Cowdin,

Portland, Oregon. Secretary, Northwest Millwork Association

Upholstering and Trimming

Further Variations in Down Upholstering

Description of the Operations Involved in Covering an Arm Chair in Which New Ideas Are Introduced

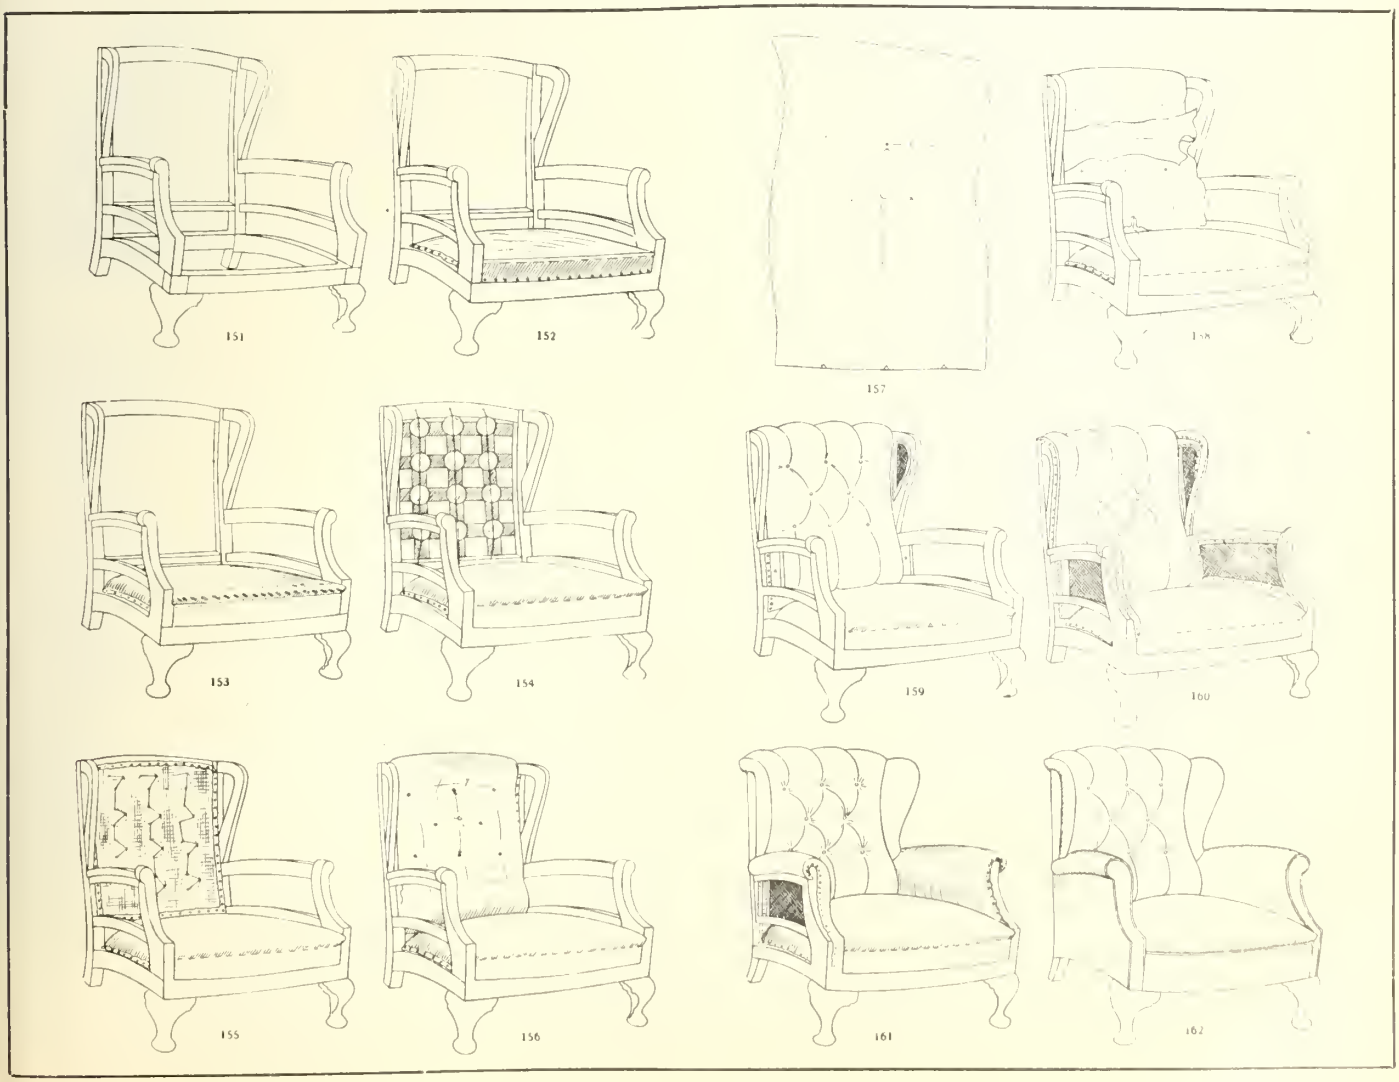
The chair frame illustrated in Fig. 151 is usually made with a buttoned back, and in order to vary the explanation of the use of down upholstering, as given in previous issues, we are treating the upholstering of this chair in a very different way from those already covered in this series.

The seat is upholstered with a spring edge, the wire of the spring edge being kept flush with the front of the frame as shown in Fig. 152. The stitched edge, which forms part of the double stuffing, is allowed to project about one inch beyond the wire as illustrated in Fig. 153.

The back of this chair is webbed on the outside for pillow springs which are lightly sewn to the canvas as shown in Figs. 154 and 155. A light double stuffing is next brought over the back to act as a foundation for the buttoning. The back is marked for diamond tufting on a basis of about 7 by 9 inches as shown in Fig. 156.

A down pad containing about one inch of down is made according to the size required for the back as shown in Fig. 157. An allowance of one and a quarter inches is allowed for buttons between tufting points and one and a half inches all around for filling and tacking. This makes the pad about five inches wider than the back and about four inches longer, but these allowances are only approximate, actual measurements would have to be made on the chair itself.

Now, with the pad as a covering muslin, having been marked for buttons, the back of the chair is stuffed up in the ordinary way for diamond tufting, the pad forming a soft top stuffing but being handled just as a covering muslin would be handled, being



careful to keep the top and bottom covering of the pad in their proper relationship.

It is a good plan to mark the button points on both the top and bottom of the pad. This is best done by punching the marks through with an awl while the pad is stretched out on the table for stuffing. This gives a mark on both the top and bottom which can be kept in line as each tuft is pulled into place. See Fig. 158.

After the back has been completely tufted and the edges tacked as shown in Fig. 159, the arms and wings are canvassed leaving space where each joins the back so that the covering of the back can be brought through and tacked to the back side rail as indicated at the left of Fig. 159. Blocks are placed between the top and bottom rails of the arm as shown at X in this figure and a wire is put in the back edge of the canvas of the wings and securely tacked.

The next step is the nosings for the arms and wings which are applied after the manner we have already illustrated in connection with Figs. 26 to 33.

The chair will now have the appearance of Fig. 160. The arms and wings are lightly stuffed so as to obtain the greatest degree of softness as shown in Fig. 161 and the completed chair trimmed with welts and panels is illustrated in Fig. 162.

Good Light Important in Upholstering Shop

Impossible to Accomplish Good Work in Ill-Lighted Work Rooms—An Abundant Supply of Natural Light Necessary to Match Fabrics

A trip through the average furniture plant will demonstrate to the visitor how little concern is given to the matter of light in the upholstering department, and yet in no trade is a good supply of both natural and artificial light more essential than in that of the upholsterer. Very frequently the upholstering department is forced to accommodate itself in a basement or some out-of-the way corner where the only daylight is that which struggles through window areas or small, inadequate light wells. Of course, the manufacturers attempt to augment the scanty supply of natural light by installing some form of artificial lighting, but even this is usually so inadequate as to be practically useless.

It has been recognized that the lack of good light seriously interferes with the quality of workmanship and with the health and producing capacity of the workmen, but it almost appears as if the upholstering shop is the last to be studied in this connection. How often do we see bright surroundings in the finishing department and in some of the cabinet-making sections of the plant, but, on the other hand, dingy and dull quarters for the upholstering staff.

It is almost needless to say that it is impossible to accomplish good work in ill-lighted shops, and there are many reasons why this state of affairs should not exist to-day. Bad light is often the indirect cause of faulty construction in upholstery work, especially in the case of leather, velvet and shaded fabrics. Frederick Palmer, a well-known English instructor in upholstering methods, comments on this phase of the subject as follows:— "In the case of leather work it is impossible to shade and blend the skins. The reader may easily test this for himself. Let him examine, say, an easy chair in Morocco first in artificial light and then in daylight. In the former the leather may appear to be one color; in the latter he will find maybe five or six different shades that cannot be toned together correctly in artificial light. The work in such conditions is liable to look patchy and to offend the eye. Velvets are very difficult to match up by artificial light. Some of them possess four distinct shades by reversing back to front and right to left, and where many cuts are to be made mistakes soon occur. All this shows how necessary it is that the upholsterer's shop should be one where a maximum of daylight prevails, and a minimum of artificial illumination.

"The right to work in a good light is one upon which the upholsterer should always insist. It means all the difference between a good and a bad week financially, to say nothing of the inevitable effect on the quality of the work done.

"Next to light, a good benchway, with plenty of space, is important. It often happens that where coverings for the work in hand are not available, the upholsterer may have several jobs in progress at the same time unfinished. Hence, the need for plenty of room, especially where there are many men employed. A side-bench, about 4 ft., 6 in. wide and 3 ft. 6 in. high, fixed beneath the windows, with divided bins beneath for the various stuffings, serves the double purpose of a cutting-board and a place for unfinished work. The bins should be boarded up half-way, and divided into 5 ft. or 6 ft. lengths.

"Trestles should be about 36 in. wide and 30 in. high with grooved tops, to insure a frame remaining rigid when placed on them. It is necessary to have a high pair and a low pair, the latter to be used for settees or chairs with extra high backs; they will also be found useful in many other ways.

"Cutting-boards for marking out should be made about 6 ft. 6 in. by 4 ft. for the large, and 3 ft. 6 in. by 5 ft. for the smaller sizes. These should not be of too soft a wood, as with the constant hammering and pritchawl holes, the wood soon splinters, and the board becomes useless."

Practical Points on Finishing

Don't overload the surface with liquid filler, varnish, enamel undercoating or enamel. If you do the result will be a thick coat that will crack and flake off. In using liquid fillers, enamel undercoatings or enamel, in order to insure the adhering or gripping of the coats to each other, see that they are thoroughly mixed. Thin coats mean quick hardening.

To avoid an uneven appearance, exert the same amount of pressure all over the work. Hold the brush at right angles to the face of the work, which is thus touched by the end of the brush only.

Don't dip the brush too deeply, nor allow any of the finishing material to enter the stock of the brush. If you do you will spoil the brush as well as the work; the material up in the stock of the brush can not be removed easily and will harden there. This will get the brush out of shape and cause tiny particles of the hardened material to deposit on the work, making it specky.

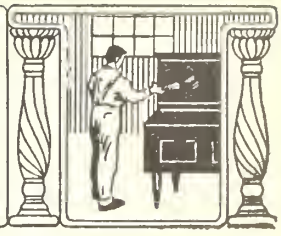
THE FINISHING ROOM



Mechanical Equipment Supplants Hand Methods

The Modern Finishing Department's Efficiency is Vastly Increased by the Use of Varnish Sprayers, Machine Rubbers and Similar Devices

It was not so many years ago that the finishing department in the majority of plants was practically devoid of mechanical equipment of any kind. The various operations from the first filling or staining to the final rubbing and polishing were all performed by hand. All this has changed, however, so that today the reverse holds true, and in the finishing room of some of the more up-to-date factories practically all the operations are performed mechanically.

One of the most far-reaching developments in this direction was the perfecting of the spray machine. This was originally sold for applying varnish with the aid of compressed air but the tendency in recent years has been toward applying all finishing coats with the "varnish sprayer." In many plants today, practically all the materials used, filler, shellac, enamel, varnish and lacquer, are applied through the spray gun.

This practice is not as widespread as it might be, but at that the trend is toward an ever-increasing use of the spray equipment. In some plants, where the output warrants it, separate spray machines have been put in operation to handle each kind of material. Thus one machine is kept going on stains, another on shellac and so on. There are certain advantages to this practice, for not only is each machine permanently adjusted to handle one particular class of material, but the operators become skilled in applying and working with one class of finishing material with the result that both work and material are handled to the best advantage. In other plants where the volume of work going through does not warrant such a large number of machines, each sprayer is used for more than one finish, although it is customary to provide separate hose and "guns" or nozzles for the various materials. This does not mean a separate hose and nozzle for each finish applied but it would hardly do to handle white enamel through equipment that had just been used for applying stain or filler.

More Work When Spray Equipment is Used

The head of one finishing room recently remarked that he was thoroughly sold on the idea of applying all finishes with spray equipment and had adopted this standard practice in his department. He has found that each spray machine will turn out as much work as from four to eight finishers and in many cases the coats are applied with greater uniformity. In the case of certain stains it is often advisable to have a finisher stationed near the spray booth to brush the articles as soon as they are sprayed. This results in an even distribution of the stain and takes care of any runs that might otherwise occur.

He intimated that his policy was to break in green operators rather than attempt to train finishers for the work. His reason for this was that not only do skilled finishers often object to operating a sprayer but in addition, they usually have a number of fixed ideas as to how various finishes should be handled and applied, with the result that they are not prone to follow instructions and the work often suffers. Green hands follow fully and carefully all instructions, have no preconceived ideas either with regard to the way the various materials should be handled or with regard to the quantity of work which should or should not be put through. When once broken in and trained they usually make the best operators, turning out a satisfactory volume of well finished work.

Other pieces of equipment that are aiding production in finishing departments are special rubbing machines. These may be either portable or stationary and driven by air, electricity or belts. In many plants all the larger flat surfaces are machine rubbed and often light portable rubbers are used on the smaller surfaces. However, while such equipment saves considerable in time and money, hand rubbing is not entirely eliminated for it is usually found necessary to have hand rubbers follow the machine and in addition there are many places the machine will not touch. As in the case of spraying equipment the output of the department can be materially increased by using rubbing equipment wherever possible.

This reference to the finishing room equipment would not be complete without some mention of special drying apparatus. Not only does the use of varnish drying kilns give complete control of the drying operation but it permits the development of drying schedules which may be followed without any noticeable variation. Under the old regime a coat of varnish, for instance, might require anywhere from twenty-four to seventy-two hours to dry, depending entirely on atmosphere conditions. With the drying apparatus in use, every day is an ideal drying day with the result that the average drying period runs usually from eight to twelve hours. This equipment conserves both time and space and permits the finishing department to be put on a regular production basis, working on a definite schedule.

No mention has been made of special conveying equipment, usually in the form of everhead carriers, or of special dipping machines. These can hardly be classed as regular equipment although each might be used to advantage in the average plant. The day may come when even these labor-saving devices may be found in every finishing department but for the present the development is toward the use of spraying, rubbing and drying equipment to an ever-increasing extent.

Modern Finish Drying Schedules

With Up-to-date Equipment and Accurate Control of Humidity and Temperature, the Time of Drying is Reduced and Greater Production Ensured—Conveyor Dryrooms

This article follows the one in the last issue entitled "Night Finishing a Waste of Time and Space."

How the small modern dryrooms can be adapted to the highest grades of finish is illustrated by the following figures and Diagram No. 3. In a plant formerly equipped with the old style box oven, no attempt being made to control the humidity of proper circulation, records show that the average schedule is as follows:

Stain applied in the daytime, dried overnight;

Filler applied in the daytime, dried overnight;

Shellac or shellac substitute applied in daytime, air dried overnight;

First varnish coat applied in the daytime, dried overnight;

Second varnish coat applied in daytime, in dryroom overnight; air dried twenty- four hours;

Third varnish coat applied in daytime, in dryroom overnight; allowed to set six to eight days before rubbing.

Time in finishing department, fifteen to seventeen days.

With modern drying equipment to insure the proper circulation, and accurate control of humidity and temperature, the following schedule can be maintained every day in the year:

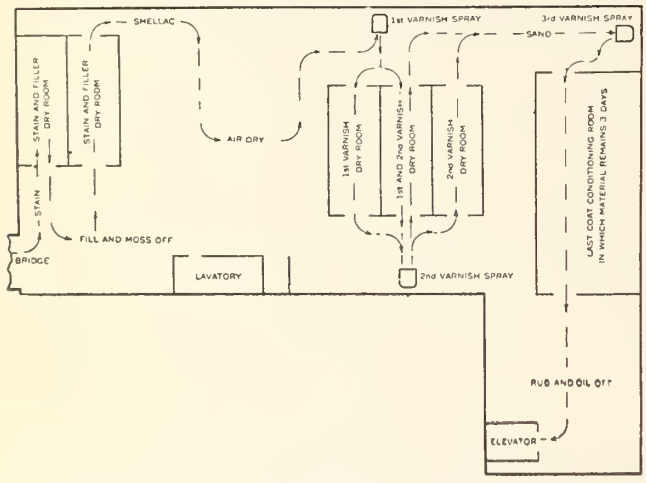


Diagram No. 3—Small modern dryroom, adapted to highest grades of finish

First day—Stain and filler, two drying operations, 120-degs. temperature, 38-40 percent relative humidity.

Second day—Shellac-sprayed in daytime, air dried over night.

Third day—First varnish coat applied in daytime, dried from six to eight hours, by 10 p.m. of same day, at 116 degs temperature, 40-42 percent relative humidity.

Fourth day—Second varnish coat applied in daytime, dried from six to eight hours, by 10 p.m. of same day, at 116-degs temperature, 40-42 percent relative humidity.

Fifth, sixth and seventh days—Third varnish coat applied in daytime, then allowed to remain in the conditioning dryroom for three days, temperature in same being approximately 108-degs. and 48 percent relative humidity on the dry bulb and 88-degs on the wet bulb.

By this schedule, work removed from the conditioning room can be immediately rubbed, making the total finishing time seven to eight days. The release in material in the course of production is over 60 per cent. In one case where this type of equipment was installed, there was a release of over 160 piano cases on a daily production of 16 to 20 cases.

Another example of dryroom installations which applies to a large number of manufacturers, is what is known as the "alternate arrangement" whereby one air washer-humidifier and heating equipment takes care of two dryrooms, as in Diagram No. 4.

For manufacturers whose output is varied, and whose mill equipment will not permit a very close schedule day to day, this alternating arrangement offers the very best solution for the finishing room drying problem. With this system there is generally a dryroom ready to receive the material as soon as it is coated, and floor space which would normally be used for air-drying storage becomes a dryroom housing. The drying equipment is designed to take care of one room, but the productive dryroom area is equal to one and a half times the total dryroom space.

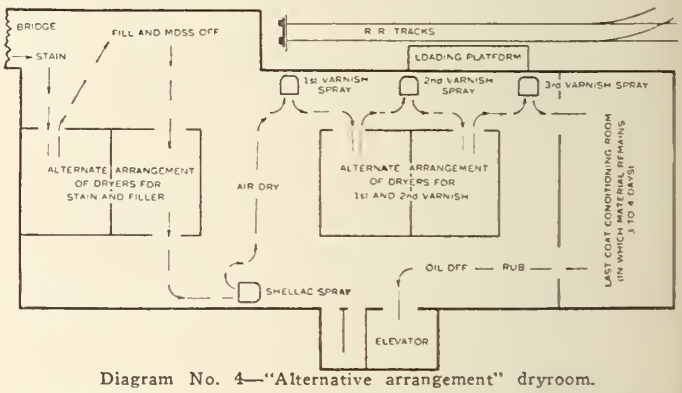

Diagram No. 4—"Alternative arrangement" dryroom.

Last Coat Conditioning Room

The last coat conditioning room shown on Diagrams No. 3 and No. 4 was specially developed to meet the requirements of the phonograph cabinet manufacturers, who are required to finish a definite number of cabinets every day, but many of the leading furniture manufacturers have also seen the advantage of this method of conditioning the last coat, over the conditioning of the entire finishing room.

In general, the method of operation consists in building a dryroom with sufficient floor space to hold from three to five days' production, depending upon the quality of finish and number of coats. Each day's output is placed in a certain space or row as it is coated, and there it remains for a definite period under temperature and humidity conditions until removed to the rubbing deck.

The average time for medium grades of finishes is three days, at a temperature of 112-deg. on the dry bulb and 90-deg. on the wet bulb. Certain long oil finishes require five days, and special piano finishes seven days; but in every case the time formerly required between the application of the last coat and the rubbing application is cut in half.

The investment for the last coat conditioning room equipment is very much less than for equipment to condition properly the entire finishing room. The cost of operation is also decidedly lower because all the space is utilized for drying, there be-

ing no waste space above the articles. The heat losses are negligible on account of the relatively low temperature required.

The last coat conditioning room eliminates the atmospheric variations which occur when coatings are allowed to stand between the last coat and the rubbing operation. These variations are caused by the cooling down of the factory temperature during the night time in the winter months and the high increase in the relative humidity during the night time in the summer months and are generally recognized as one of the main causes of poor finish and delays in the finishing process.

In the last coat conditioning room, by holding the coating at a constant temperature and humidity during the night time as well as the day time, these variations do not exist and there is the big saving in the rubbing operation because the surface is absolutely free from dust and dirt.

Diagram No. 5 illustrates the two types of conveyor dry-room now in use for the drying of finishes in the woodworking industry.

There are many types of finishes and many instan-

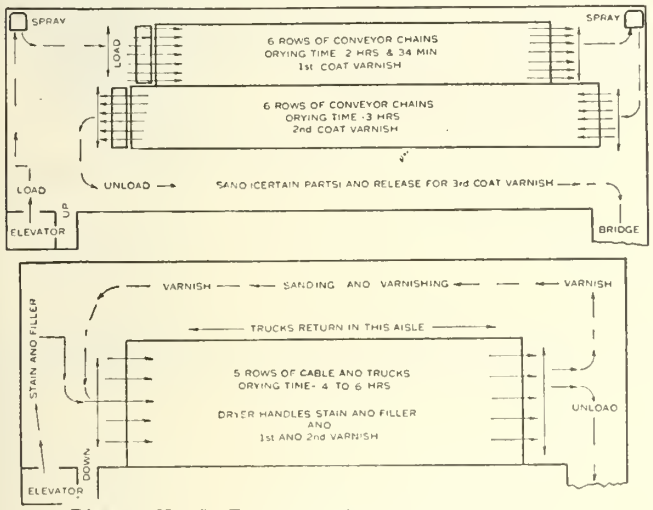

Diagram No. 5—Two types of conveyor dryrooms.

ces where there is sufficient quantity production to warrant the installation of conveyor dryrooms in the woodworking industry and so far the number of installations has been extremely limited. One of the reasons has been the high cost of the conveyor equipment on account of the length of time in drying. The other has been the lack of knowledge on the part of the purchaser on how to make a time study of his work so as to proportion the dryroom to take care of as nearly as possible the average amount of material per daily output.

The advantages of drying on a conveyor are self-evident to anyone who has seen one of these systems in operation.

The productive dryroom area is 100 per cent. It is always a dryroom, there is no loading or unloading. The proper temperature and humidity can be so regulated and arranged in zones within the dryroom so that the coating is dried under ideal conditions and more rapidly than in the box type.—By C. H. Currier, in Veneers, Indianapolis.

The varnish brush should be selected with a view to the size of the surface that is to be coated—a large brush for a large surface and a small brush for a small surface. A varnish brush that is too small for the job will cause rough work.

A Few Practical Varnish Pointers

Heavy-bodied varnish should not be brushed out much; it should be applied in a full, flowing coat.

Varnish demands light and air in order to dry right, and appears to dry faster in daylight than in darkness. Some say two to one.

The varnished objects require warmth until perfectly dry, this especially in chilly weather. Do not place a freshly-varnished job in a cold or cool room.

Cleanliness in every part of the work is necessary in order to insure good work. This means everything clean.

If the varnish is too thin it will not produce a full-bodied coating, while a too-heavy-bodied varnish will not flow out well. Light-bodied varnishes flow out well and do not show the brush marks as heavy varnish is apt to do.

Before varnishing be sure that the surface is free from dust or dirt, grease or moisture, these things causing blotching. This blotching may also be caused by thinning the varnish with turpentine and not getting a perfect mixture. Blotching is also called pin-holing.

Ordinary varnish may be said to require twenty-four hours for drying, but some others will demand two or even three days, and this the expert varnisher understands. Some varnish will dry very soon, upon its surface, while certain others will dry all the way through, but will require more time.

Putty and Puttying

The economy of quality is demonstrated in the purchase of putty. Good putty goes further, is much easier to use and gives more satisfactory results than poor putty. Adulteration of putty with fish, mineral and rosin oil is common. Its detection is easy; the oil will separate after standing in the package for about fourteen days and come to the top when it may be easily compared with linseed oil. Putty made with linseed oil turns hard after a reasonable time to a uniform mass without the oil separating. Another good test for putty that has a mineral oil odor, is to make a small cone of the putty and touch a lighted match to it. If it has been made of mineral oil it will burn like a candle.

Sand and marble dust are also used to adulterate putty and in excess quantities will cause it to crumble. Sometimes adulteration can be detected by reducing the suspected sample to the consistency of paint. By pouring this on glass and working with a putty knife, grit will immediately be noticeable if sand or marble dust is present.

The adulteration of putty will retard the drying of finishing materials and cause white enamel to turn yellow.

Good putty will cling well, dry well and can be sandpapered easily. It is poor policy to add additional drier to the putty as furnished by the manufacturer because this will usually cause it to contract in drying and sink, leaving a depression as well as a crack at the edge.

Putty should be pressed into the holes evenly, applying neither too much not too little and so spreading and finishing off without rims at the edges that little sandpapering will be required.

Putty should be as nearly as possible the same

color as the surrounding finish. A flexible knife should be used in applying, being careful not to dig into the wood. To prevent rims at the edges, a piece of cloth is sometimes used. Ridges left to harden will be hard to remove. Pressing the putty well in makes it less likely to sink or swell. Care must be taken that the putty does not dry too hard, because in that case it is apt to contract in drying and sink, leaving a depression as well as a crack around the edges.

When finishing in the natural finish most finishers make the putty a little darker than the wood, as most woods darken with age.

Should you have an accumulation of dried-out putty, by cutting these lumps into small chunks, and placing in a pail of water, just enough to cover the putty and adding a little oil, allowing it to get quite warm, even hot, on the stove, the putty will absorb the oil and the water may be poured off.

To make putty dry hard, add a little plaster of paris or red lead or use turpentine with the oil when mixing. Where putty fails to dry hard, owing to non-drying mineral oil being used as an adulterant, use red lead or litharge to dry it.

Dusted Walnut Finish

The wide popularity of walnut is bringing out experiments in individuality and efforts to produce special effects. One of these is what is termed dusted walnut, with which also goes a polychrome finish on some of the solid foot and frame work that goes with the walnut paneling. The idea back of it seems to be to get an age rather than an antique effect by a special treatment that shows a whitish dusting here and there and this, combined with the polychrome stain effect, is being pretty strongly featured now. It is probably an outgrowth of the desire to get individual character in the furniture, and whether it will grow into wide use or become merely a passing fad remains to be seen.—Veneers, Indianapolis.

You are worth what you earn. When you are worth more you will earn more.

A good factory lumber inspector is one of the best investments a manufacturer can make.

If a circular saw was put on the ground and run at the same speed as it does in the bench how many miles would it travel in a day?

The wood finish that will not paper mark in shipment

A product finished with ZAPONITE, the Pioneer Wood Lacquer, is proof against the harmful effects of paper marking when wrapped and packed for shipment.

Being extremely hard and uneffected by moisture, heat and climate changes, a ZAPONITE finish never gets "sticky," it never paper marks and it never shows the imprint of burlap wrappings—another reason why ZAPONITE is the ideal finish for quality products made from wood.

Let our Service Division help you to determine how ZAPONITE can be used in finishing your products at a SAVING in your production costs. Write us about this service TODAY.

Increasing the Speed and Decreasing the Cost

of Your Finishing Room Operation

How practical, how advantageous and how dependable DeVilbiss spray-painting equipment is, has been demonstrated in finishing rooms of every size and line.

Not merely in dozens of finishing rooms, but in thousands of them. Not only where a few different kinds of articles are handled, but where every kind, size and grade of wood or metal product is finished. Not alone where varnishes, enamels or lacquers are used, but where every kind of liquid finishing material is applied. The

DeVilbiss

Spray-painting System

offers a complete, adaptable and guaranteed service. The finishing operation is speeded up 4 or 5 times over hand-brushing. A perfect, uniform coating is applied on all jobs. Working conditions are made more healthful and safer. Operating and upkeep costs are reduced to the minimum.

With your consent, we'll gladly tell you whether and how the DeVilbiss System can be of service and profit to you.

The New Standardized Shade

"Brown Bird's-Eye Maple"

As Featured During the Summer Markets

HAVE you received your panel showing this new standardized shade, Brown Bird's-Eye Maple? A color that your foreman can easily produce when he once sees a sample panel.

You will agree, when you see Brown Bird's-Eye, that it is the most striking and beautiful wood obtainable for two-tone effects, bedroom suites, inlays, overlays, decorative panels, novelty furniture—in fact wherever rich contrasts in warm color tones are desired.

Nature has ornamented Bird's-Eye with a figure which cannot be duplicated. And now the craftsman's experience has enriched the handicraft of Nature.

We will be glad to have your finishing house send a sample panel that will show you exactly how striking an effect you may obtain with this new finish. This, of course, places you under no obligation.

The Core is Where the Trouble Often Lies

Furniture that is Supposedly High-Grade is Frequently Marred in Appearance Through Faulty Core Drying

By S. H. Johnstone

"What makes the best core for veneered tops?" was the question a furniture manufacturer fired at a lumber salesman the other day. "A perfectly dry one," came back the salesman. The reply was unexpected, for the furniture maker thought the lumberman would name some one species of wood as his choice for core work. There is little doubt but that it is important to make a wise selection in choosing lumber for this foundation work, but of even greater importance is to make sure that it is perfectly dry.

In many plants the commonly accepted conception of a core is that it is something to be covered up and as a consequence any kind and grade of wood that will hold together is usually worked into the cores. This same attitude of, one might say, contempt is also largely responsible for the fact that little, if any, attention is given to the condition of the stock itself. By condition is meant its dryness.

Finished Product Spoiled by Poor Cores

In selecting lumber for this work the stock must be reasonably sound and should be free from large knots and large checks. While it is true that the core is totally covered and is thus hidden from view, it is also true that the beauty of what would otherwise have been an attractive veneered surface is often marred because of some defect in the core. This was brought forcibly to my attention the other day when examining a handsome and expensive dining-room suite. The design, workmanship and finish of this exquisite suite was all that could be desired but in a certain light I noticed that the perfection of the top was marred by a defect due to a large knot in the core stock. From the appearance of the top the knot had been knocked out and the hole filled with some compound. The result was as I have stated. Had this been a cheap suite of furniture, one could at least understand, if not excuse, how a core of that kind might have been allowed to go through, but in the production of high class furniture where quality rather than initial cost should be the prime consideration, it is unexecusable. Nor do those things just happen. Rather they indicate a weakness somewhere. It would appear that those responsible either do not know or do not care. Ignorance or carelessness of this kind is not a legitimate excuse.

Some of the more common defects to be noticed in veneered work are sunken joints, wide depressions running lengthwise of the work and a wavy, washboard appearance. All of these are due to an uneven distribution of moisture in the core at the time it was surfaced and thicknessed. If all the pieces going into a core are not uniformly dry those that contain the most moisture are going to shrink the most as they come into equilibrium with the rest of the core and with surrounding conditions. It often happens that this equalizing or drying does not occur until after the stock has been veneered and sanded. The result is that when the drying and equalizing does finally end, one or more depressions are to be be found on the veneered surface of the work. The remedy is to as far as possible put none but uniformly dry pieces into core work and then as an extra safeguard plan sufficiently far ahead to allow plenty of time for the moisture in the stock to equalize before planing or sanding is done. When this is done it is likely that there will not be any more trouble from sunken joints, for these in turn are due to too much haste in surfacing after the joints have been glued.

I have seen cores taken from the clamps as soon as the glue has set sufficiently to hold the work together and run through the planer. It stands to reason that the wood on either side of each joint is in an expanded condition, due to the moisture absorbed from the glue, and when this wood finally dries out or equalizes, after being planed, narrow depressions commonly known as sunken joints, form along each joint. If the veneering operations have been rushed this shrinking often does not occur until after the surface has been veneered and finished, in which event the sunken joint becomes plainly visible on the finished surface.

Make up Cores Well in Advance

It should be possible to establish a number of standard sizes for multiple cores, that is cores which will cut without excessive waste into a number of different sizes. If that were done it would be practical and advisable to keep a number of these multiple cores made up well in advance. When an order comes along the multiple cores that would cut to the best advantage would be selected and worked up. By following some such idea as this would be quite feasible to make up all cores well in advance, as it would not be necessary to carry a large stock of individual sizes.

If this is not considered to be workable it might be well to get out the cores for each lot, and joint and glue them before an attempt is made to break out any of the other parts. It is a mistake to try and rush the cores through to the veneer room. More than that it is not enough to allow them to be stacked around the shop for a few days but they should be carefully piled on trucks with sticks between each piece and given a chance to dry as well as equalize.

Giving a little extra attention to core work in this way would add very little to the cost of production, probably not enough to show on the cost records, but it will make a real difference in the appearance

and saleability of the finished article. More than that, as the general public come to know what to expect in veneered furniture and refuse to buy that which does not come up to the mark, the producers of veneered articles will be forced to give more attention to the cores. It is not, however, advisable to wait until sufficient pressure is applied to compel that none but perfect veneered work be placed on the market. It would not take very much effort in the way of educational publicity and constructive salesmanship to put over in a big way, a line of really well built veneered furniture. A good market avails the individual or organization that first sells well made veneered work on its merits.

Methods for Making the Adhesive Strength Test of Glue

Several Methods that Have been Proposed are Described in Detail—A Rough Test for Use in the Glue-Shop

By R. H. Bogue, Ph.D.*

On account of the many factors which enter into any test upon strength, on account of the skillful technique necessary in order to obtain reliable and comparable data, and on account of the rather elaborate equipment required for properly making the test, the strength test has not received the universal attention in glue evaluation that might have been expected. In lieu of the actual strength test many other tests upon certain properties, as jelly consistency, viscosity, and melting point, and analyses for certain chemical groups, as α gelatin, β gelatin, etc., have been proposed as being true indications of the real strength value. One or another of these propositions have been quite generally accepted by the glue trade, and as a result very few consumers include an actual strength determination in their specifications. One of the exceptions to this has been the specifications of the National Advisory Committee for Aeronautics for glue to be used on airplanes, but the tests were made by the Service at the Forest Products Laboratory.

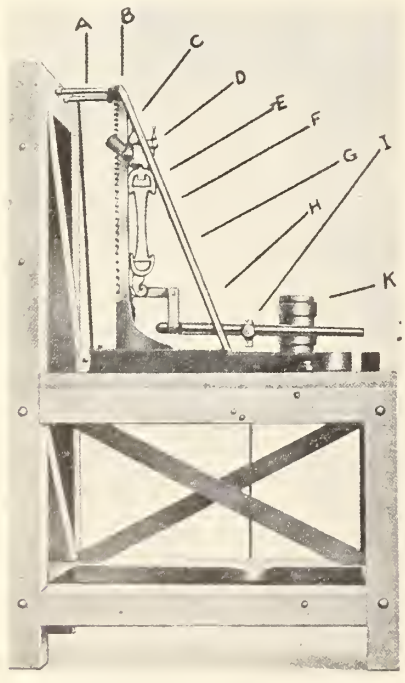

Fig. 1 (a)—The breaking machine used by Kahrs

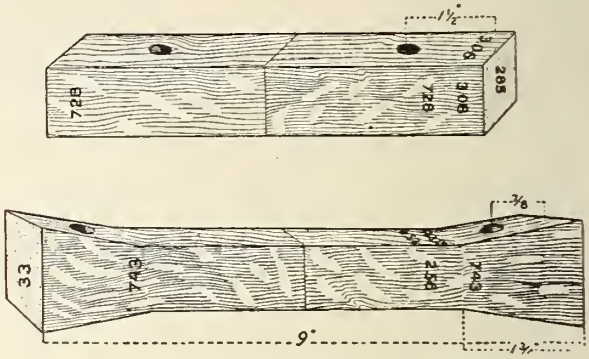

Fig. 1 (b)—The test pieces used by Kahrs

The methods that have been proposed for making the strength test are briefly described below.

Kahr's method.—Kahrs used blocks of well-seasoned oak, glued end to end, the area of the joint either 1 square inch or 1.44 square inches (one hundredth part of one square foot). The length of the former type of block was 4½ inches, and a shoulder was left at the end away from the joint to impart greater strength. The blocks were glued together after a careful weighing and measuring and varnishing, placed between clamps and later broken apart. For this purpose holes were bored near the ends of the blocks, steel pins inserted, and by means of an improvised machine, pulled apart. The machine used was of a lever type, the placing of weights at various

(When writing mention Canadian Woodworker)

points on the lever arm exerting a measured pull at the joint. The blocks and machine are illustrated in figure 1.

Gill's method.—Gill first made briquettes of fuller's earth, diatomaceous earth, quartz sand, and sawdust, using glue as a binder. These were dried at 80 degrees for 6 days, and broken by the well-known cement briquette testing machine. Difficulty was experienced in drying completely, the briquettes were full of blow-holes, and no consistent results could be obtained.

Gill then used rectangular prismatic maple blocks, sawn into a special form as shown in figure 2 and having an end area of one square inch. The blocks were glued end to end, and a uniform pressure secured by placing in a frame wherein the pressure employed was determined by placing weights on a lever arm bearing upon the joint. The pressure was maintained for 3 hours, and the joints allowed to dry at room temperature for 2 to 4 days. They were then pulled apart in the cement testing machine, after the ends had been blocked up with bronze blocks to fit the briquette holder of the machine.

Rudeloff's method.—Rudeloff applied the glue solution to the planed end surfaces of two pieces of red beech wood, 185 mm. long, 125 mm. broad, and 50 mm. thick, and placed the blocks so that the glued surfaces crossed at right angles. A definite joining pressure was used, and "the force required to tear

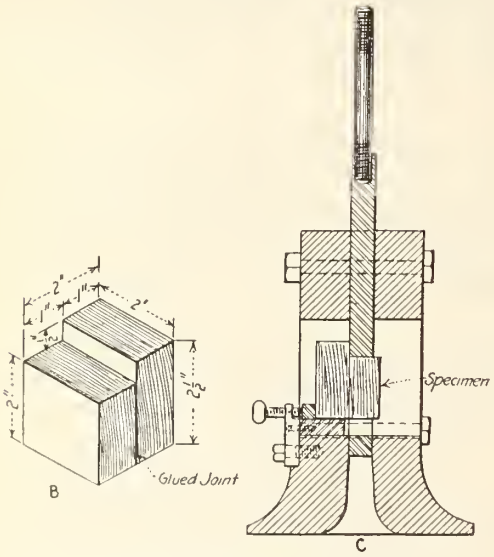

Fig. 3—The shear block test specimen and testing tool used by the Forest Products Laboratory

the pieces of wood apart measured by means of a suitable machine." He later used both edge and flat grain joints of beech, ash, oak, and fir, using 50, 40, 33-1/3 and 25 per cent glue solutions at a joining pressure of about 5 kg. per square centimeter, (about 65 pounds per square inch). Individual tests varied as widely as from 63 to 102 kg. per square centimeter.

Forest Products Laboratory method.—The method developed by the Forest Products Laboratory at Madison, Wis., is as follows: Two blocks of hard maple about 1 by 2½ by 12 inches in size are glued together, subjected to a definite pressure, allowed to dry out for a week, and cut into blocks as shown in figure 3. The glued area of each block is exactly 4 square inches. One of the two pieces is permitted to extend a half inch beyond the other to facilitate the technique and prevent a slip in the shearing process. The blocks are broken by placing in a shearing tool, as shown in the figure, in which pressure is applied upon the end of the smaller block until the joint separates. This pressure is most conveniently obtained by the use of a universal testing machine, by which the exact pressure at the breaking point may be read directly.

If the break occurs entirely in the glue, a measure of the strength of the glued joint is obtained, but if,

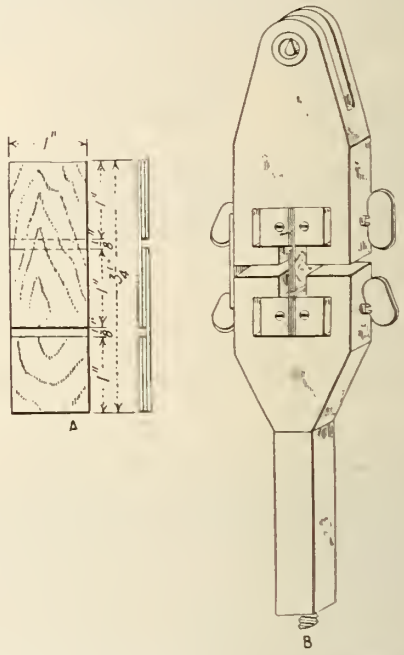

Fig. 4—The plywood test specimen and plywood shearing tool used by the Forest Products Laboratory

as frequently happens, the break takes place partly or wholly in the wood, the breaking pressure is less than the strength of the glue, and in order to obtain more exact data the test must be repeated with a stronger wood. The shearing strength of hard maple,

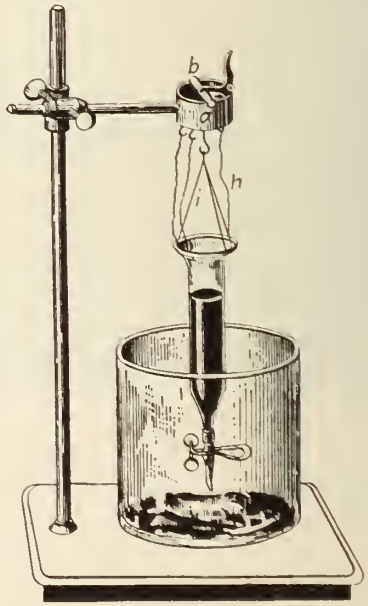

Fig. 5—Wiedenbusch's strength test

using similar blocks, is about 3,200 pounds per square inch, so the exact strength of glue which is stronger than this cannot be measured upon maple. The results obtained by this method are reasonably satisfac-

JAMESTOWN, N. Y.

Our claim to superiority is not based on the flimsy reason that it is good because WE make it. Our Veneer is superior because of certain definite operations that make it a better article. A thoughtful analysis will verify these statements.

N. B. Veneer is put up in a workmanlike manner. It is a clean, merchantable product. Defective or split ends are CUT OFF—not marked out with crayon. Dead or stained sap, or otherwise defective edges are ripped off. We leave the waste here, giving you a refined article.

We guarantee our measurements. Our inspectors are careful, accurate and thoroughly experienced. We welcome a remeasurement of our flitches. A comparison with other manufacturers will impress you favorably with our methods of measuring.

We maintain a critical inspection department. Every flitch is stamped with inspector's initial, and branded N. B. This maintains the identity of our Veneer, symbolizes the responsibility we assume, and is emblematical of the pride, skill and painstaking care that prevails throughout our entire operation.

N. B. Veneer is worth the price asked.

Methods for Making the Adhesive Strength Test of Glue

(Continued from page 82)

tory, and by taking the average of several breaks, the test becomes entirely practicable.

An additional strength test is made upon glues that are intended for plywood manufacture. The form used is the one adopted by the British and American governments for the testing of aircraft plywood. It is shown in figure 4. A piece of the plywood 3¼ inches long by 1 inch wide is sawn so that the inner section is cut through from opposite sides leaving a section of one square inch. This is then placed in a machine, as shown, designed for testing cement, but provided with special grips. The section is subjected to tension and fails principally from shearing.

Wilmers' method.—As an illustration of the way in which the strength test may be employed by any glue-shop foreman, and as an example of the more "advanced" of the modern glue-shop methods, may be cited the suggestion of Welmers. He glues two pieces of wood together measuring 1 by 8 inches, edge to edge so that a right angle is formed. One of the arms of this angle is fastened vertically into a rack on the wall, while a beam is secured to the horizontal arm. At the end of the beam is hung a pail into which water is allowed to run evenly and slowly. The weight of the pail with its contents at the breaking point of the joint is the measure of the glue strength. Such tests as this are, of course, crude, but if made with proper care some indication of the relative strength should be obtained. It is at least a beginning, and if glue consumers realized the advantages of such tests, it would not be long before a more standard and a more accurate procedure would be generally adopted.

Heinemann's method.—A different type of adhesive test has been used by Heinemann. He suggests that a determination of the minimum strength of a glue solution that exhibits a definite adhesive power on paper be taken as a measure of glue strength. Strips of strong smooth paper were used; one brushed over with, say, 1 per cent glue solution, another strip of paper laid over the first, and pressed under a 5 pound weight for 1 or 2 minutes. The paper is then taken up, and it is observed if the joint will support a weight. Heinemann found that at or about the critical degree of dilution the joint will either support a fairly heavy weight—even as much as 30 pounds—or scarcely no weight at all. All measurements are referred to a standard for evaluation.

Other methods.—Settenberg soaked strips of unsized paper in a solution of glue of definite concentration, pressed the strips between blotting papers to remove the excess of glue, and when dry broke them in a paper testing machine by tearing tests.

Weidenbusch prepared exactly equal prismatic rods of gypsum 9.2 cm. long with the sides of the transverse section 4 mm. and having a weight of 1.7 grams. These were dipped in a glue solution for five minutes, then removed and allowed to dry. The rod is then placed across an iron ring, as shown in figure 5, and a dish hung to the center of the rod into which weights are placed until the rod breaks. Weidenbusch claims to have obtained fairly consistent results by this means, but Gill has found such methods unsatisfactory.

Hauseman first employed blocks of "biscuit-ware" stone which he glued together and subsequently pulled apart. Not obtaining satisfactory results by this means he next used pieces of straight grained walnut 9 x 2 x 3/8 inches in size. These strips were glued so that 4 square inches of surface was in contact, and after leaving in the clamps for 48 hours, and curing for a further 24 hour period, they were sheared apart.

Lumber Air Dried by a Revolving Machine

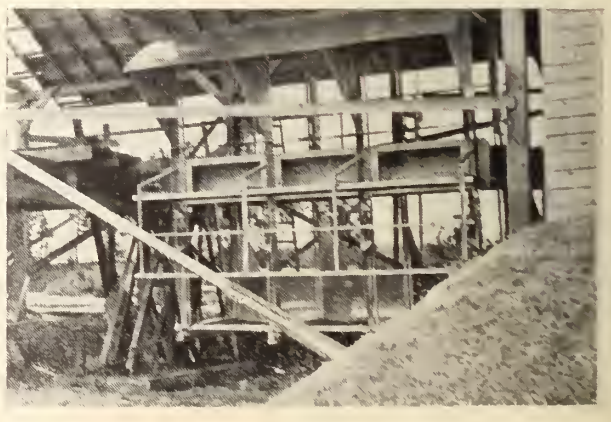
The Method Consists of Spinning the Stock at Eighty Revolutions per Minute—Suction Opens Cells of the Wood and Removes Moisture

A new process for the natural drying of lumber by means of a centrifugally operated machine has recently come to the front in Canada. The standard type of machine which revolves on a six-inch steel shaft, accommodates 4,000 feet b.m. at one loading, but larger ones can be furnished if desired. The time required for loading spinning and unloading the lumber is two hours. The production, operation and capacity of this patented invention is described by a correspondent of the "Canadian Woodworker" who recently paid a visit to the scene of its activity as follows:—

This machine was constructed and installed at a sawmill north of Sault Ste. Marie, Ont. I visited the plant and spent ten days there during which time the machine and process were thoroughly tried out.

In the morning we had green logs of birch and pine hauled out of the lake where they had been for several weeks. They were cut up in the mill and in the afternoon the lumber was spun on the machine, then removed from it and allowed to stand in the open for one week. The result was that the lumber was reduced in weight 34% from the green log, or as against the dry lumber 52% of moisture was removed.

The principle of the operation is so far as can be ascertained as follows:—The 6-inch steel shaft has a steel framework on the upper and lower side, each ca-



The centrifugally operated machine for air-drying lumber

C. L. WILLEY COMPANY

The Largest Veneer Plant in the World

FROM your viewpoint, the value of the WILLEY plant lies not alone in the quantity and quality of Veneer at your disposal, through the great variety and rarity of these treasures of the world's forests which we possess, but also, and especially, in the trained judgment and thoughtful consideration with which we select the most perfect specimens for your particular purpose.

A vast stock, and a world-wide organization constantly replenishing it, enable us to fill your orders with gratifying promptness.

Veneer & Lumber

American and Circassian

Mahogany
Quartered Oak
English Oak
Satinwood
Vermilion
Teak
Rosewood
And Many Other Foreign and Domestic Woods

(1884)

Living Marble

THE resemblance between the grain of beautiful veneer and the veining in beautiful marble lies deeper than a mere chance arrangement of lines. The slow, orderly deposit of matter by blind forces of nature, in response to unchanging law, produced them both.

But marble is lifeless—while wood is a product of life-forces, an unfolding of protoplasm, a growth from within. Therefore we choose elegantly veined marble for a monument or a tomb, but enrich and soften the dwellings of living people with the gracious penciled lines of forest growth, made visible and enduring as Veneer.

For the selection of figures and wood best fitted for the particular work you have in hand, the WILLEY plant affords unexcelled opportunities.

Ask us for samples.

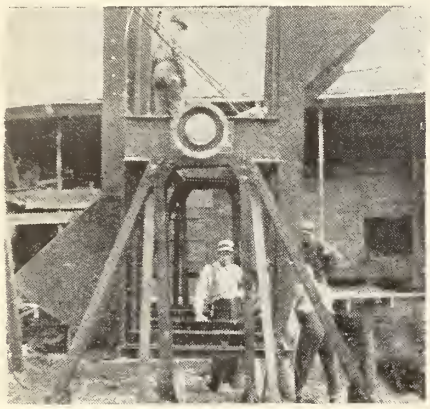
pable of holding 2,000 feet b.m., (standard machine), or a total of 4,000 feet b.m. The lumber is piled from the sorting table on to a buggy or truck with the usual 1-inch stripping and with 2,000 feet is run into the upper frame of the machine, which is securely locked in, then turned over and a similar truck load is placed in the lower or other half of the machine. This is also locked in and power turned on to revolve the outfit.

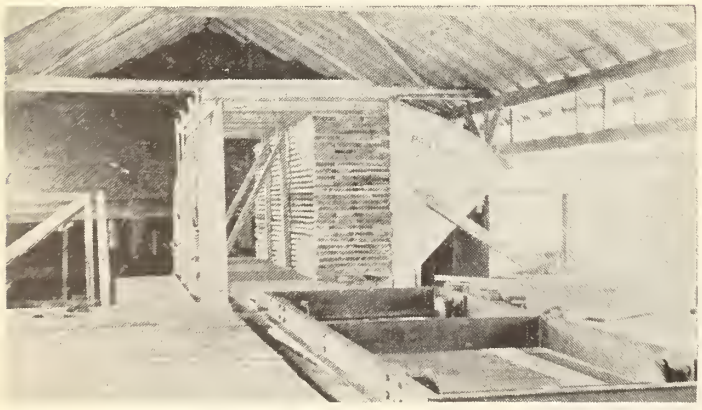
The machine is revolved at the rate of 80 revolutions per minute. The intakes are so adjusted that the air goes in at the rate of 40 miles an hour, creates a vacuum and comes out with a pull of 80 miles an



End view of the machine showing air intake wings

hour (by actual test). This intense pull or suction apparently opens the cells of the wood and sets up a syphoning action and once this action is set up, the trucks are taken out and side-tracked and the lumber allowed to stand, the moisture continuing to come out until at the end of the week it shows the difference in weight as that already cited. The lumber shows no signs of checking or warping and some of the birch was recently made into a table top for a leading furniture manufacturer with excellent results, and this without having to resort to a dry kiln.

The power necessary to operate the machine is 8



Section of the air-drying machine partially loaded and in the foreground a truck ready for loading

to 10 h.p. The other agent is the free air, no heat being required.

The 4,000 feet b.m. machine can be loaded five times per ten-hour day, thus giving 20,000 feet b.m. at the end of one week and that quantity of dry lumber daily thereafter during the operation of drying plant. About 3,000 or 4,000 baseball bats were dried out and manufactured during the winter with the thermometer at 30 deg. below zero. The wood turner who made them, has been at the wood turning business for thirty-five years and stated, when he saw logs frozen solid, hauled into the mill, cut up, put through the machine and at the end of the week given to him to turn into bats, as dry as any wood he ever handled, that he was astounded. Those were all made of birch and ash and at the present time show no signs of check or twist. Some of these bats were placed in a dry kiln for four days at 150 deg. and came out intact.

A charter has just been granted to the Natural Air Dryers Corporation, Limited, Toronto, who are already placing some of the machines in Canada and the United States.

Production of Shellac

It is safe to say that funriture manufacturers and finishers are not as a rule very conversant with the production and peculiarities of shellac which is one of the most essential materials employed in their finishing departments. Shellac is a derivation of lac, which is a resinous incrustation produced on certain trees in India, Indo-China and Siam by the lac insect. The incrusted twigs are known as stick lac. When crushed this lac becomes seed lac or grain lac, so-called because of its resemblance to seeds or grain. Melted and dried in shell-like flakes it becomes shellac. When formed into the round flat shape of a button or the elongated oval shape of a tongue, the lac is known respectively as button lac and tongue lac. These two forms, though they can be made from any grade of stick lac, are usually made from medium to good grades. Garnet lac, another form in which lac is marketed, is dark red melted into a thin slab form but not reduced to flakes.

Practically all the lac comes from British India, which furnishes about 41,800,000 lbs. against 1,400,000 lbs. exported by Indo-China and Siam. India's figure is even more predominant than these figures indicate, however, because much of the lac exported from Indo-China and Siam is stick lac while that from India is mostly clean lac rosin in the form of shellac, button lac or seed lac. In the last three years shellac has comprised on the average 89% of the lac exported from India.

Shellac has a very wide application in many lines of industry, but, of course, the use in which the furniture trade is interested is as a preservative coating for wood and metal in the form of vanrishes and lacquers. For use as a varnish, shellac is dissolved either in alcohol or by the use of an alkali in water. Denatured and wood alcohol are commonly used, but for special purposes the more extensive grain alcohol may be used. Shellac is insoluble in turpentine and linseed oil and hence is valuable for first coating woodwork, as it seals the surface, closing the pores and soft grain so that an even surface is obtained over which the top coatings can be applied with an assurance of permanence and evenness.

Shellac is graded according to its lightness of color and freedom from dirt and insoluble matter. About half of the shellac manufactured is of the grade known as "T.N.," an abbreviation for "truly native." Though of comparatively low quality and of rather dark color, it has a large consumption where cheapness is more essental than light color. This grade is usually manufactured with a mixture of rosin. Adulterations to shellac have to be guarded against, as, especially in times of high prices, considerable quantities of rosin and occasionally sugar are added.

The Lumber Market

Domestic Woods

The hardwood market continues fairly active with an increasing number of inquiries and firm prices. There have been some advances, particularly on firsts and seconds and No. 1 Common in chestnut, and firsts and seconds in plain and red oak; otherwise quotations remain very much the same as they have been for some weeks past. There is a strong demand for maple and birch is also having a good call. The principal shipment of these woods is to Detroit ,Buffalo and other United States points.

Some complaints have been heard with reference to the car shortage, particularly in the East. The Transportation Committee of the Canadian Lumbermen's Association is taking up the matter and hopes to report an improvement in conditions in the near future. The secretary of the Railway Association of Canada says there are 19,000 box cars on United States lines in excess of the United States cars on Canadian lines. This is 9000 more than usual, due to the fact that American cars were held up by the strike of railway shop employees and the big demand for rolling stock for hauling coal. The American railways will not return Canadian cars if it can be avoided. On the other hand, complaints are made in Quebec that Canadian cars are not unloaded promptly, and it is alleged this fault rests with the railways themselves. It is expected, however, that from this on there will be a gradual improvement in the situation. This particularly affects a number of Canadian wholesalers who have not been able to secure deliveries of southern hardwoods, orders for which were placed many weeks ago.

There is an improvement in a number of the woodworking industries. Door and hardwood flooring plants are particularly busy; in fact a number of these establishments have sufficient orders on hand to keep them going for the next six or eight weeks.

Hardwood lumber producers still complain that the low ends are not finding a ready market and that prices are altogether too low. One Northern Ontario firm says that no operator can find his stumpage, log it properly, mill the product, handle it several times, pay insurance, keep his plant up and remain on speaking terms with his banker at the low value which No. 3 common in birch and maple is sold at to-day. "It must be remembered," he points out, "that there is no over-cut in hardwood. Latent defects prevent it. It often happens that a very fine log after the slab is off will develop a defect running through half the length of it. Maple, perhaps, more than any other wood, covers up wounds received at different times in its growth. The producer of hardwood lumber should receive, at least, double the price, it is contended, that the softwood manufacturer secures, for he handles two tons to the other's one. He gets no over-cut, recovers a very small percentage of high-class lumber and is offered for his class a figure that does not pay the saw bill. "And," concluded the speaker, while consumers may be looking for cheaper lumber, it cannot be hardwood. On the contrary there must be an increase in the price of hardwood if the manufacturer is to receive even a small profit, and he is entitled to that."

There appears to be a feeling that lumber in certain grades will be scarce by next spring if the demand is at all normal as seems possible that it will be. This, of course, would mean higher prices, and no one wants to see a runaway market. The stabilization of values and production is the desideratum of all branches of the trade at this particular period.

Imported Woods

Reports from all the hardwood centres of the United States seem to indicate that business is on a better plane than it has been for some time. Orders seem to be extremely plentiful, inquiries are numerous and distribution is taking place as fast as cars can be obtained; in fact it was reported that it is doubtful if there ever was a fall season in the history of the business when trade was so active as this fall. In place of the retail demand falling off, it seems to be increasing and the only fly in the ointment is the car situation. This car scarcity is interfering with shipments, of course, and distributors report orders that cannot be filled. The volume of new construction in the United States continues very heavy and as a consequence lumber is in demand. Furniture factories, too, seem confident that they will have a big winter business. This is partly due, of course, to the vast amount of residential and apartment house construction. Box makers as a rule report a notable increase in their activities, indicating a general speeding up of industry all along the line. The piano and phonograph trade is somewhat slackening, due to the season, but automobile companies are hard at work on closed jobs for winter sales and as a consequence there is considerable lumber for this purpose in demand. Reports from three of the leading centres are as follows:-

Memphis, Tenn.—Transportation facilities are governing the hardwood situation at this point. There appears to be plenty of demand with orders coming in in great numbers. The only difficulty is that consumers are urging prompt shipment and there is difficulty in handling them owing to the lack of suitable transportation equipment. It is stated that inquiries and orders are now larger than they have been for more than two years and that the industry is on the eve of a tremendous revival, as soon as it is possible to make shipments on a larger scale. Furniture, automobile and flooring manufacturers are very active in the market while other lines seem to be requiring large amounts of lumber.

Louisville, Ky.—Louisville hardwood producers claim that they would be doing a fine business if the car situation were normal. The demand for all kinds of lumber and veneers is exceptionally good, all lines of the wood-using industry being in the market. Prices are somewhat advanced due to the fact that movement from the far-distant producing centres is slow and stocks on hand are commanding a premium.

Evansville, Ind.—In spite of the car shortage the hardwood lumber manufacturers in this vicinity report a somewhat increased demand and they are looking for a splendid business for the balance of the year. Prices are holding firm. In this section of the country it is stated that there is some improvement in the car shortage situation. All branches of the wood-working industry are in the market but ash, poplar, white oak and gum are the woods that are in most demand. If cars are available, most of the manufacturers are expecting a big winter business.

HAY & CO., Limited Woodstock, Ont.

News of the Trade

The Anglo-Canadian Company, Iberville, P. Q., are contemplating building a two-storey factory to cost $5,000.

Security Box Co., Montreal, was registered recently with Harry Lehman as principal.

National Auto Body Co., was recently registered at Montreal.

The Gotfredson-Joyce Corporation, Ltd., Walkerville, Ont., have started excavating for a $20,000 addition to their factory.

The Sturgis Baby Carriage Co., Sumach St., Toronto, have postponed the erection of their new factory at Brampton, Ont., until next spring.

The Woodstock Pipe Organ Builders, Ltd., lately installed a $12,000 organ in the Simpson Avenue Methodist Church, Toronto.

James Brookes Woodworking Co., New Westminster, B. C., was recently awarded the millwork contract for the new Canadian Memorial Church at Vancouver, to cost $55,000.

The Seaman, Kent Co. are erecting at Meaford ,Ont., a large concrete building for housing sawdust. The structure is 35 x 40 feet and 29 feet high.

Parlor Furniture Manufacturers, Ltd., Victoria St., Point aux Trembles, P. Q., was damaged by fire recently to the extent of $75,000.

Pembroke Plywood Co., Pembroke, Ont., have leased the old Pembroke Iron Works buildings and are installing machinery to manufacture veneer and plywood.

A. W. Carmichael, Limited, Toronto, is a new company incorporated with provincial charter to manufacture and deal in all kinds of building supplies. Capital $250,000.

Daniel Sinclair, of the Sinclair Carriage Works, Lindsay, Ont., was drowned recently when returning to town from his summer home in a motor boat.

Royal Brush Company, Hamilton, Ont., was recently granted a provincial charter to manufacture and market brushes, brooms, felt wheels and other similar articles. Capital $40,000.

Mr. L. Yarwood, manager of the Canada Toy & Novelty Manufacturing Co., Smith's Falls, Ont., spent a few days recently in Toronto on business in connection with the sale of the products of the company.

A. L. Reid Co., Ltd., Toronto, were recently incorporated to conduct a business as dealers in builders' supplies. Capital $40,000. A. L. Reid and P. W. Ninnes, both of Toronto, are two of the incorporators.

J. Lemages, Terrebonne, P. Q., was awarded the millwork contract recently for the new 32-suite apartment house at Outremont, P. Q., which will cost $200 000. The lumber contract was given to L. Villeneuve & Co., Outremont.

Thomas Hayes died recently at his home in Champlain St., Quebec City, in his 83rd year. The late Mr. Hayes was an expert ship's carpenter and was much sought after to build racing shells for sculling matches on the St. Lawrence River.

A very successful Made-in-Owen Sound Exhibition was held in that city. Interesting and attractive displays were made by the Keenan Woodenware Mfg. Co., Limited, and the Eureka Refrigerator Co. Both these firms occupied considerable space and their showing was a creditable one.

W. J. Currie, president of the Curric Manufacturing, Brandon, Man., suffered a painful accident on August 31. He was running some boards through a machine in the factory when his hand was caught and four fingers practically amputated.

The warehouse of the Keenan Woodenware Mfg. Co., at Owen Sound, Ont., was burned to the ground recently and was a total loss. It was well stocked with everything that the firm manufactures and the loss is all the more keenly felt as it occurred at the company's busiest season.

Dominion Upholstery Co., Ltd., Ottawa, is a new concern incorporated with a capital of $40,000 to maufacture and deal in all kinds of upholstery goods. M. Agulnick and H. Orkin, upholsterers, both of Ottawa, are two of the incorporators.

Natural Air Driers Corporation, Ltd., Sault Ste. Marie, Ont., were recently granted a federal charter with a capital of $200,000, to manufacture and market drying and seasoning equipment. J. M. Sinclair, manufacturer, Toronto, and W. H. Edwards, merchant, Sault Ste. Marie, are two of the incorporators.

William S. Johnson, Silver Birch Ave., Toronto, one of the original members of the Massey-Harris Company, died recently in his 71st year. When the late Mr. Johnston retired some fifteen years ago, he was general superintendent of the concern which he had seen grow from a small workshop at Newcastle, Ont.

Mr. A. E. Simmington, of Toronto, who is well known to the woodworking trade, having been connected with Scholey Bros. for 19 years, recently opened a factory at the rear of 471 King St. E., Toronto, and will manufacture spools and wood products, band saw shaping, moulding and general millwork.

The Glen Falls, N. B., factory of Clarke Brothers and Company, Limited, which concern operates a pulp and paper mill and saw mill at Bear River, N. S., also, has not been operated of late. Reopening may take place in the late fall when a satisfactory adjustment of the financial affairs of this concern may be arranged.

Merkley & Menzies, who for some years conducted a retail lumber yard and planing mill in Milton, Ont., recently dissolved partnership, Mr. Merkley having bought out the interest of his partner, D. Menzies. Mr. Merkley is well known in the lumber industry, having operated the plant for a long time as manager previous to becoming proprietor. Business during the past season has been very good in the lumber line in Milton.

The H. J. St. Clair Co., Ltd., well known manufacturers of complete store fronts, of Toronto, have recently opened a new factory at 28 Eastern Ave., Toronto. They have recently installed new machinery and are amply equipped to handle the biggest contracts in this line. They have just completed a big job for the L. R. Steel Company, at Hamilton.

The Owen Sound Stave and Shook Mills is one of the more recently organized companies. A little over a year ago Messrs. Norman Bumstead and J. H. Theaker organized the company which is located on 3rd Ave. W., in the old Grey and Bruce cement plant. The firm manufacturers a good line of barrels, kegs, etc. Right now a truck is on the road delivering apple barrels for the apple crop. The company's business is on the increase, and it should develop into an important industry.

In connection with the centennial of the town of Bridgetown, N. S., it is appropriate to refer to J. H. Hicks & Sons, widely known woodworkers. The company is not, perhaps, the oldest in Bridgetown, but is more closely associated historically than any other company doing business there. The present John Hicks, founder of the business,

Uniform Lumber Means Greatest Satisfaction To The User!

You no doubt have experienced the expense, loss of time, and loss of materials, caused by the use of improperly cured, wrongly graded, and carelessly handled hardwood.

Kraetzer-Cured Lumber is absolutely uniform in quality, properly graded, and every board plainly marked, showing the grade. To show our faith in Kraetzer-Cured products, every board is stamped with our brand.

THE KRAETZER-CURED LUMBER CO.

Because of our unusual facilities we control the lumber from the virgin growth to the time it is loaded on the cars and shipped to you.

When you have once used Kraetzer-Cured Lumber you will not be satisfied with the ordinary kind. Read the eight important reasons why Kraetzer-Cured Gum is used by thousands with such satisfactory results. It will give the same results to you.

Kraetzer-Cured Lumber is of the very best quality, carefully handled by all departments. Every step in this process is taken with the idea of producing uniform high grade hardwood that w ill give maximum service in your hands.

In addition to Kraetzer-Cured Gum, we can furnish Oak, Ash and other Southern Hardwoods.

The Kraetzer-Cured Lumber Co.

GENERAL OFFICE: GREENWOOD, MISS.

Band Mills: Greenwood, Miss., Moorehead, Miss. Leflore, Miss.

You Should Use KRAETZER-CURED GUMWOOD *Because:-*

1. It is STRAIGHT and FLAT, free from the warp and twist usually encountered in untreated stock.
2. It is BRIGHT and will satisfactorily take any finish.
3. It is free from dote or rot—the sap and gums are eliminated by the steaming process, and fermentation and decomposition are thus prevented.
4. Through the elimination of stain and decomposition, it possesses greater strength and longer life.
5. It contains only atmospheric moisture, enabling it to be used for many purposes without kiln drying.
6. When kiln drying is necessary, this can be done in much less time and with more satisfactory results.
7. It is uniform and dependable. One car like another, grade and measurement what it should be—no time w a s t e d in reporting complaints or shortages, no delays or interference with factory schedules because of holding lumber for adjustments.
8. It is the most economical lumber available. It will satisfactorily answer any requirements expected of materially higher priced woods. Join our little army of satisfied users, and just as peace is about to supplant war, let peace of mind take the place of the warfare and worries that usually beset the user of lumber.

We're proud of this product —that's why.

follows in direct line from the first John Hicks who settled there in 1763. The firm started in a very modest way thirty years ago, growing steadily each year until now they employ over one hundred men. Mr. John Hicks says they have experienced a very active year in their business.

Walsh Bros. operating a woodworking plant in Chatham, N. B., have been doing good business through the summer and early fall despite the general depression in the lumber trade. This concern has been established in Chatham for many years and manufactures doors, sheathing, windows, etc. It is one of the well known industries of the North Shore of New Brunswick.

Montreal capital is said to be interested in a project for the building of a woodworking plant at Woodstock, N. B. A site has been inspected and it is said construction will start in the spring. It was originally planned to build the factory in the early fall of this year but this intention was abandoned in the hope that prices of building materials and labor would drop next spring.

The Kentville Woodworkers, Limited, Kentville, N. S., have been shipping from their factory through to points in different sections of the Maritime Provinces casings, door jambs, sheathing, doors, etc. This firm has been busy all through the summer, and there is the expectation of continued good business all through the fall and winter. Although most of the firm's trade is through the Annapolis Valley, there are calls from other sections.

With the advent of the hydro-electric current in St. John, N. B., from the station on the Musquash River at Musquash, it is expected that woodworking factories in lower New Brunswick can be operated at one-half the present cost of power. Woodworking manufacturers are watching with much interest the present battle between the New Brunswick Power Company and the United Organizations of St. John on the question of private and municipal distribution of the current.

The Victor Woodworking Company, Limited, with factory at Amherst, N. S., are busy in their plant on orders for doors from Moncton and Amherst. This company has succeeded in securing much business from Prince Edward Island, shipments being made over the Tormentine branch of the C. N. R. to Cape Tormentine and thence by ferry across the Northumberland strait to Point Borden.

The woodworking factory of Murray and Gregory Ltd., St. John, N. B., which concern also operates a saw mill and art glass plant in connection, has been busy since spring. This woodworking factory is not so evident to the people of St. John as the other woodworking industries owing to its situation near the Reversible Falls. And yet the Murray and Gregory woodworking plant has been an active industry for many years. The leading spirit in this firm is J. Fraser Gregory of St. John. He has been one of the most prominent lumbermen in New Brunswick for many years. Mr. Gregory spent part of the spring and summer in Europe with his wife.

Christie Brothers, Limited, St. John, N. B., operating one of the oldest and busiest woodworking plants in the Maritime Provinces have the happy faculty of retaining in their employ men who have spent decades at their plant on Erin Street, and the former plant on City Road. One of their employees, Hugh Beck, has been a worker for Christie Bros., Limited, for more than twenty-five years.

A Made-in-Owen Sound Exhibition was recently held in that city and was very successful from every point of view. The wood-using industries were well represented, among them being the Keenan Woodenware Manufacturing Co., whose exhibit is shown in the adjoining illustration.

Estate of P. Brocklebank, Cornwall, Ont.

Sealed tenders addressed to the undersigned and endorsed "Tender for Planing Mill or Sash and Door factory," will be received at this office until noon **on the 15th day of November 1922,** for the purchase of the Planing Mill and Sash and Door Factory of the above situate in Cornwall, Ontario. Alternative tenders will be received for the purchase of:

"A" The Land, Buildings, Plant and Machinery etc., en bloc as a going concern.
"B" Land and Buildings only.
"C" Plant and Machinery only.

The Factory is still operating and is fully equipped with all modern machinery driven by Electric Motors of 66 Horse Power. There is a Railway Siding to the Plant served by the Grand Trunk, Canadian Pacific, and New York Central Railways.

The approximate book value of the Land and Buildings is $7,000.00 and of the Plant, Machinery, etc. $18,000.00. The highest or any tender will not necessarily be accepted.

Full particulars and description of the above can be obtained from the undersigned Trustee.

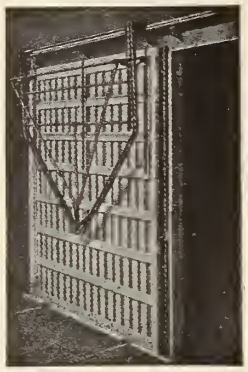
The Door Carrier System



Makes your dry-kiln doors steam-tight and saves time, heat, trouble and money.

Carrier lifts door clear of kiln and carries it down track. Returning, deposits door to rabbeted joint, where it is held steam-tight by its own weight. Applicable to old or new kilns.

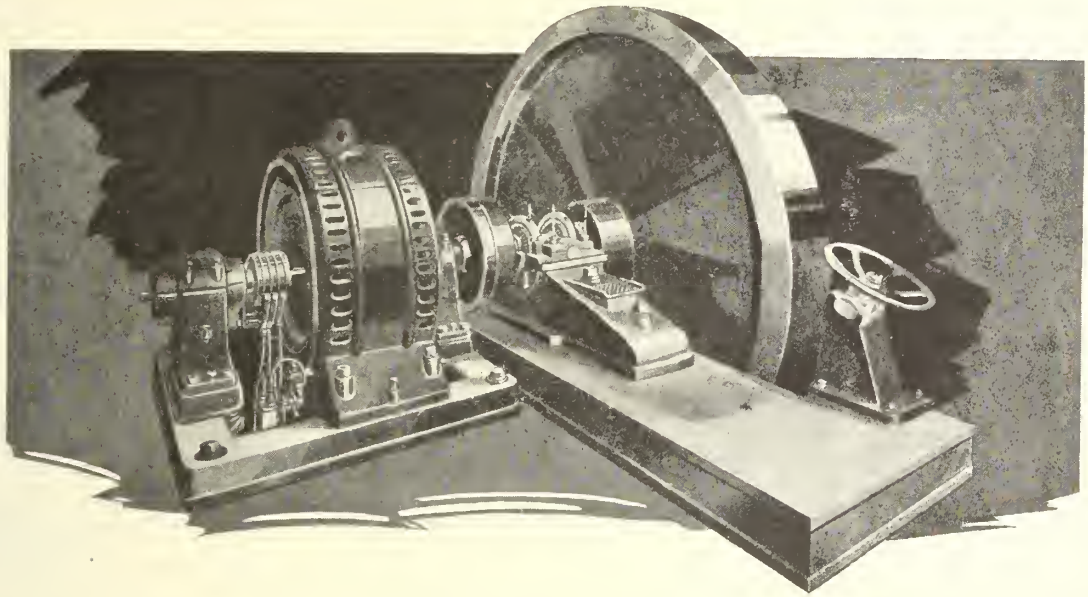
SKF



Five Hours on its Own Momentum

—An Achievement Possible Only With Ball Bearings

Five hours of motion without power! Unbelievable—but nevertheless an actual fact, as demonstrated by this fly-wheel type alternator which revolved on its own momentum for five hours.

Four SKF marked self-aligning ball bearings are used to support the revolving parts running at 500 R.P.M. and weighing 44,000 pounds.

You can imagine then the amount of energy which the use of ball bearings, as compared with plain bearings, saves in the course of a year in any plant. Since the saving in each machine is added to that of the others, the total is no mean quantity and represents a substantial increase in plant efficiency and a worthwhile economy.

When self-aligning ball bearings are used friction is practically eliminated and marked economy effected as well in lubrication and maintenance. See that your electrical machinery is ball bearing equipped.

A Record of which we are Justly Proud

THE skill, the artistry—that certain outstanding mark of the master creators of beautiful furniture are evidenced in the products of the Grand Rapids Bookcase & Chair Company of Hastings, Michigan.

We are proud to say that since 1907 Carborundum Brand Garnet Paper and Cloth have dominated in the sanding departments of this plant.

On the drum sanders, on the belt machines, in the hands of the expert finishers, Carborundum Brand Garnet Paper and Cloth enable them to maintain the highest quality of workmanship and adequate production.

Only garnet products that can cut clean and fast—that are uniformly coated with pure, sharp grain—that have strong, durable flexible backings could serve so well and so long.

Morgan No. 6 Nailing Machine

MORGAN
NAILING MACHINES
Used in Nailing Wooden Toys

Many manufacturers of American Wooden Toys use our machines for driving 5/8" to 1 1/8" nails. Machines are adjustable in operation and can be adapted to any kind of nailing work.

If you are driving nails by hand, in making boxes, crates, toys, any woodenware articles, figure the cost. It is expensive.

Then send us samples of your work. Get an estimate of the cost of nailing on a Morgan Nailing Machine. Compare the figures. We'll leave the rest to your judgment.

Send us your nailing problems. We shall be pleased to give them our careful consideration and advise you regarding equipment for handling them. We invite your inquiry.

Morgan Machine Company

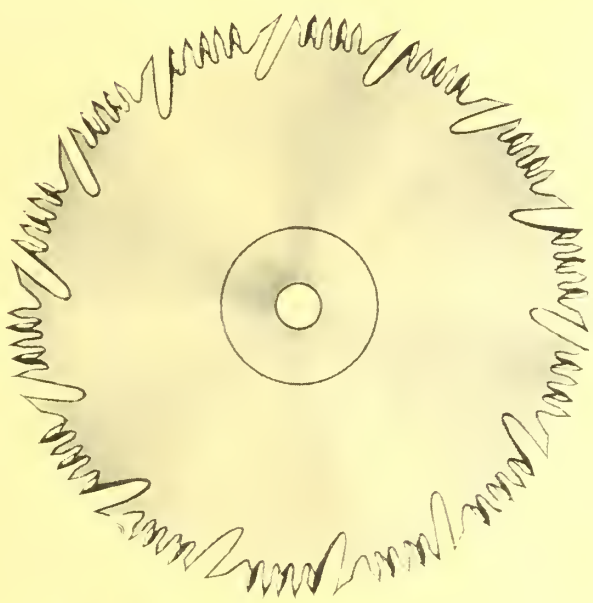
Like the Swords of Old Damascus

Beaver Brand saws and tools remain true to their careful manufacture throughout their long life.

They are like thoroughbreds, responding to every demand —saws to be relied on.

We are also agents for saw tools, machine knives, hoe shanks and bits, emery wheels, shafting, belting, files, and filing room machinery.



Give your saw repairs into the hands of our experts. Be sure that name of owner appears on each saw, and mail full instructions of work to be done, stating the hand, speed and feed of mill together with shipping directions for return of saws.

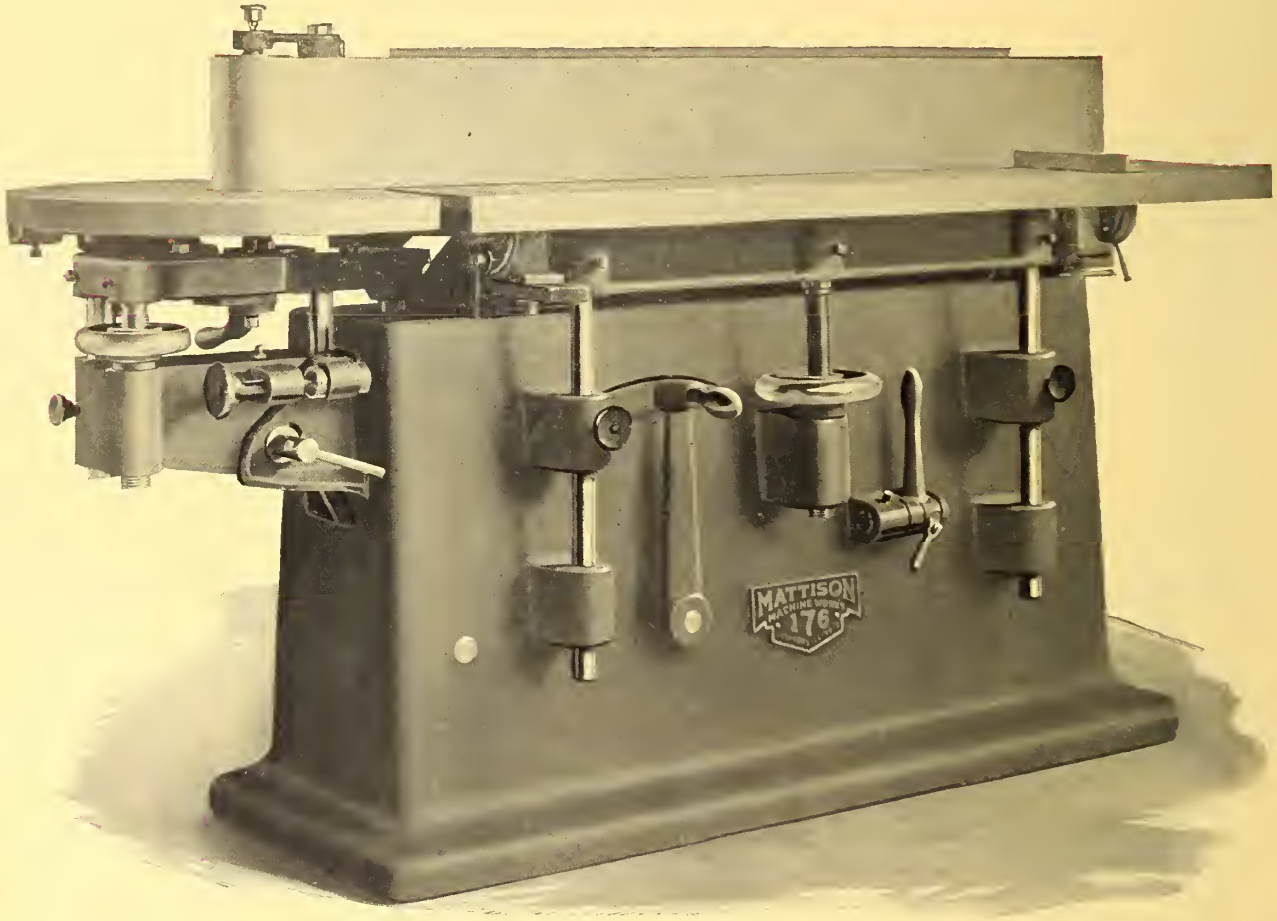
Factory—HAMILTON, Ont. **Vancouver Branch—109 Powell Street**

MATTISON
176
Oscillating-Belt Edge Sander



The Improved Model Stands Supreme

RECENT mechanical improvements place this Sander far ahead of similar types. Spiral gears have been replaced by spur and bevel gears running in an oil bath, eliminating wear. Front sanding roll runs in ball-bearings and is supported by an overhead bracket. Many operating conveniences are supplied to quicken the finishing of all kinds of edges, either straight or irregular.

Delicate work, such as the finishing of square or octagonal turnings having small ornamental members, is handled with speed and accuracy because rigid construction and vibrationless sand belt travel make the use of small spindles and narrow forms, entirely practical.

Put your sanding problems up to us. We have saved labor and increased production for others and can do likewise for you.

"Our cabinet foreman is greatly pleased with the sander, especially the oscillating movement which not only increases production, but also economizes on sand belts. We find it well adapted to scroll edge sanding as well as straight."—Macy Co., Grand Rapids, Mich.

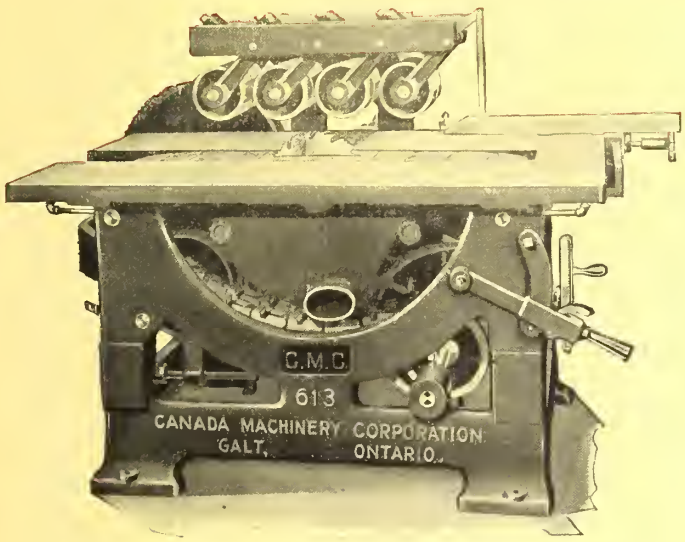
CANADIAN WOODWORKER and Furniture Manufacturer



"The Better Line"

C.M.C.

No. 613 Light Ripping and Jointing Saw

"A Profit Producer.'

The logical machine for medium ripping and jointing in furniture factories and woodworking shops.

It rips core stock so true and straight that it can be immediately glued together without further correction, and when a tongue or V joint is required, the smallest cut on a jointer is sufficient.

Saves time, stock and power. Protects the operator and produces quality work in great quantities.

Write for bulletin today.

Specialists in Wood Working Machinery

Consider the Job
-not the price

No matter what price you pay—you get just what you pay for.

A "cheap" job—done at a price—may be all right for a time, but it is found to be costly in the end—to say nothing of the inconvenience and delays that are sure to result.

When your Blower or Exhaust system is installed by us, you KNOW you are getting the service of efficient engineers backed up by years of experience.

The Toronto Blower Co.,
City.

Dear Sirs:-

I have pleasure in writing this letter in regard to the Blower Systems you installed in my factory last year. Both the shaving and the separate sawdust systems are working very satisfactorily and I know we have as good a job of piping as it is possible to put up. This work was done under the direction of your Mr. Daniels, whom I consider a very good mechanic.

Yours truly,
T. H. Hancock.

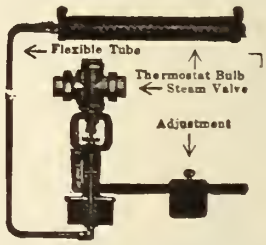
The Foster Fan lifts a maximum load and saves power doing it. Handles every conceivable kind of material—wet or dry—without clogging.

Why not send for our illustrated folder?

The Toronto Blower Co.
156 Duke St., - TORONTO

YouDon'tGuessTime! WhyGuessTemperature?

In the glue kettle, the varnish drying room, the dry kiln—wherever there is a need for maintaining a definite, even temperature, the Powers Automatic Heat regulators give "100 per cent perfect" results. They are always on the job—accurate, sure, reliable. They prevent overheated glue, checked or case-hardened lumber, crazed varnish—all the errors that are so apt to creep in with manual control.



The Powers Regulator No. 15
Entirely self-contained. Peculiarly adapted for control of drying room, kiln, etc.
Other Powers Regulators for other places. Ask for details.

We shall be glad to give you the benefit of our more than thirty years experience in temperature regulation, and if you will tell us where you would like to try out a Powers Regulator, we will send the right one for thirty days' trial. If you don't find it satisfactory, send it back.

Advantages that will Appeal to Users of Sanding Machines

Sand paper on the drums can be tightened up at each end independently or simultaneously. This is a great help when putting on the paper as it saves considerable time.

Should the paper become loose on the drums while machine is in operation, slack is taken up automatically, thus preventing paper buckling or tearing, which affords a saving in the sand paper used. The felt and paper are wound on the drums spirally, which gives you continuous cutting drums, furnishing a much smoother finish.

These are exclusive features embodied in Yates Endless Bed Sanders only.

Has automatic stop to prevent bed from running up into sanding drums. Yates Endless Bed Sanders are adapted especially for sanding narrow and short stock, taking pieces short as 3 inches. Will handle the big stock as well.

Built in three sizes 31, 43 and 49 inches wide.

Our Sander book describes this machine fully, as well as showing many different types and outlining their various uses.

P. B. Yates Machine Co. Ltd.

Hamilton - Ontario

The Invariable Choice Yates Of the Man Who Knows

YATES

The Invariable Choice Yates Of the Man Who Knows

"Fire Me"

said a progressive salesman to the Manager. "I am costing the House too much. I am spending so much of my time explaining to prospective customers who I am, who my House is, what my goods are, and why they are worth buying, that I don't have much time left for selling. Do all this preliminary work for me by means of effective advertising before I reach the Furniture Dealer's store. It can be done better and cheaper this way than I can ever hope to do it."

FURNITURE WORLD

Hugh C. MacLean Publications Limited
Toronto Montreal Winnipeg Vancouver

The wise manufacturer uses Furniture World not only to save his salesmen time but also to save the time of the Jobbers' salesmen.
The "open door" to the Furniture field is the "Furniture World" which for years has earned and held the confidence of advertiser and buyer.

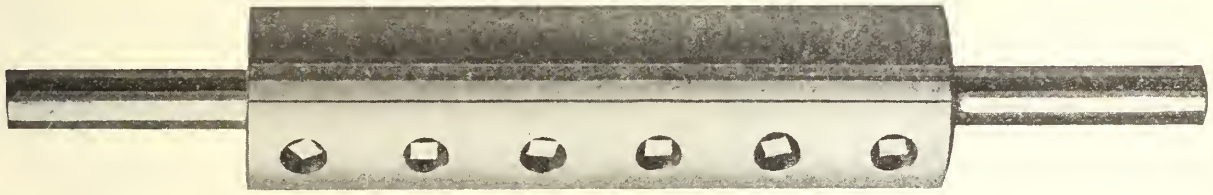
The Shimer Round Safety Cylinder with High Speed Knives



A Round Safety Cylinder that will Appeal to the Buyer and the User for three Reasons:

The first is our adjusting nut for setting the knives. It is the only cylinder with properly located adjusting nuts for setting the knives, which, with our way, can be set to 1-1000 of an inch.

The second is our way of holding the knife without tapping into the head.

The third is the correct angle of cut for the knives.

Made for any of the Different Makers' Machines and in Any Length Cylinder

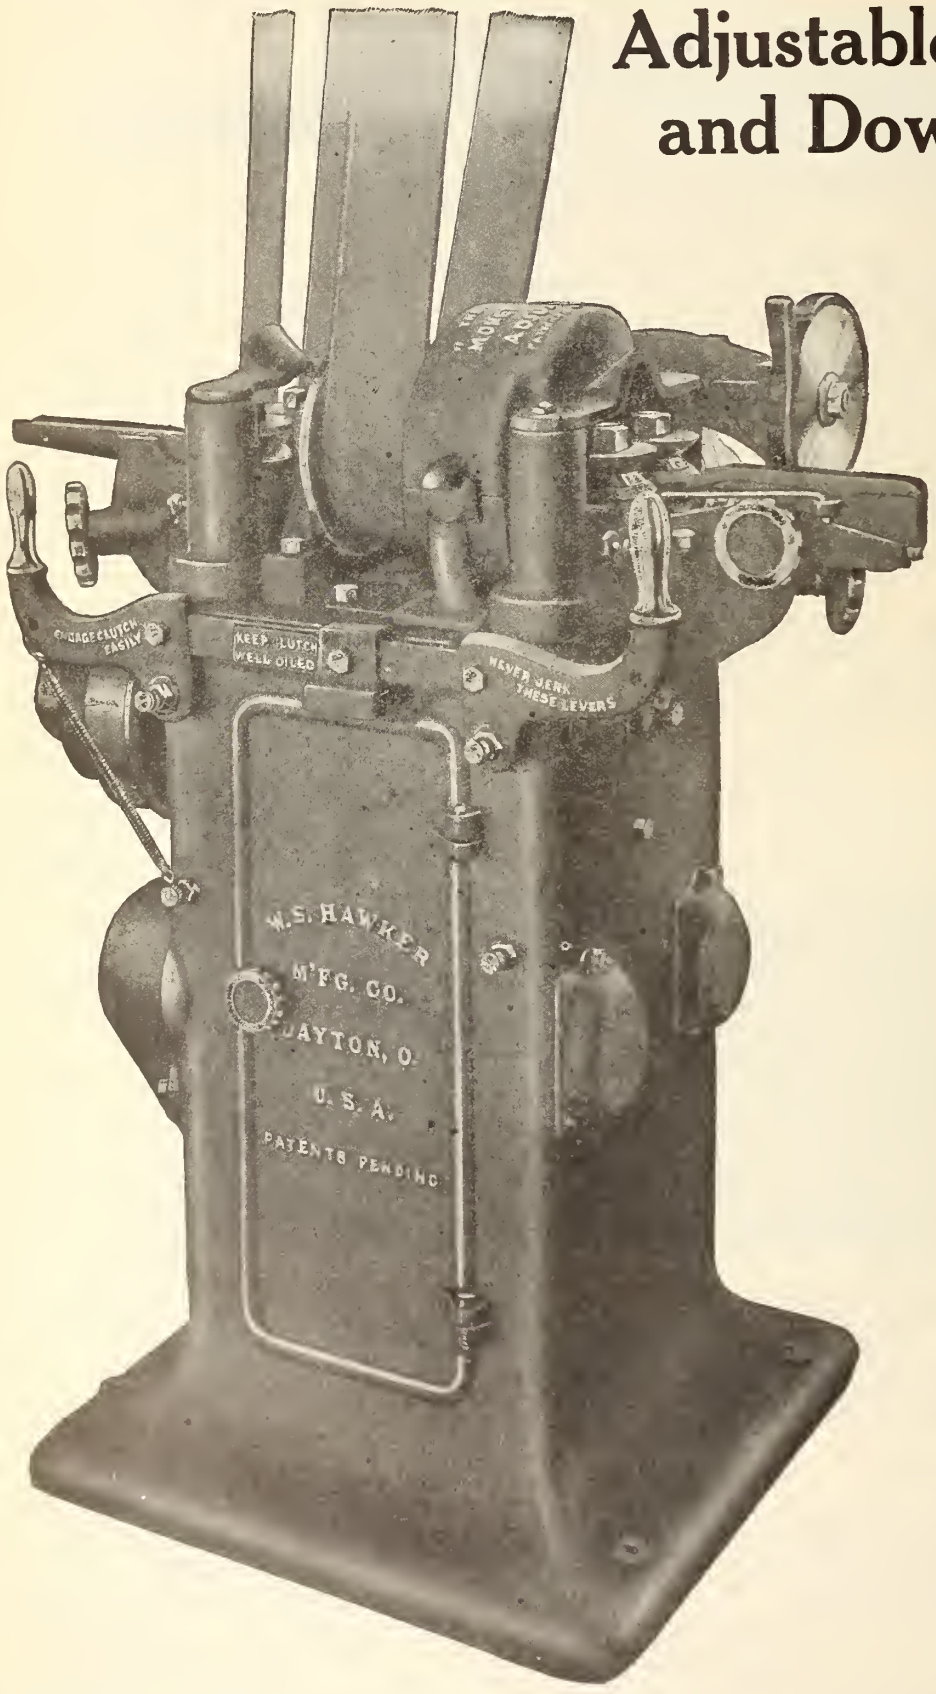
Shurly-Dietrich Limited---Galt, Ont.

Branch and Warehouse, Vancouver, B. C.

The Money Maker— Adjustable Rod and Dowel Machine



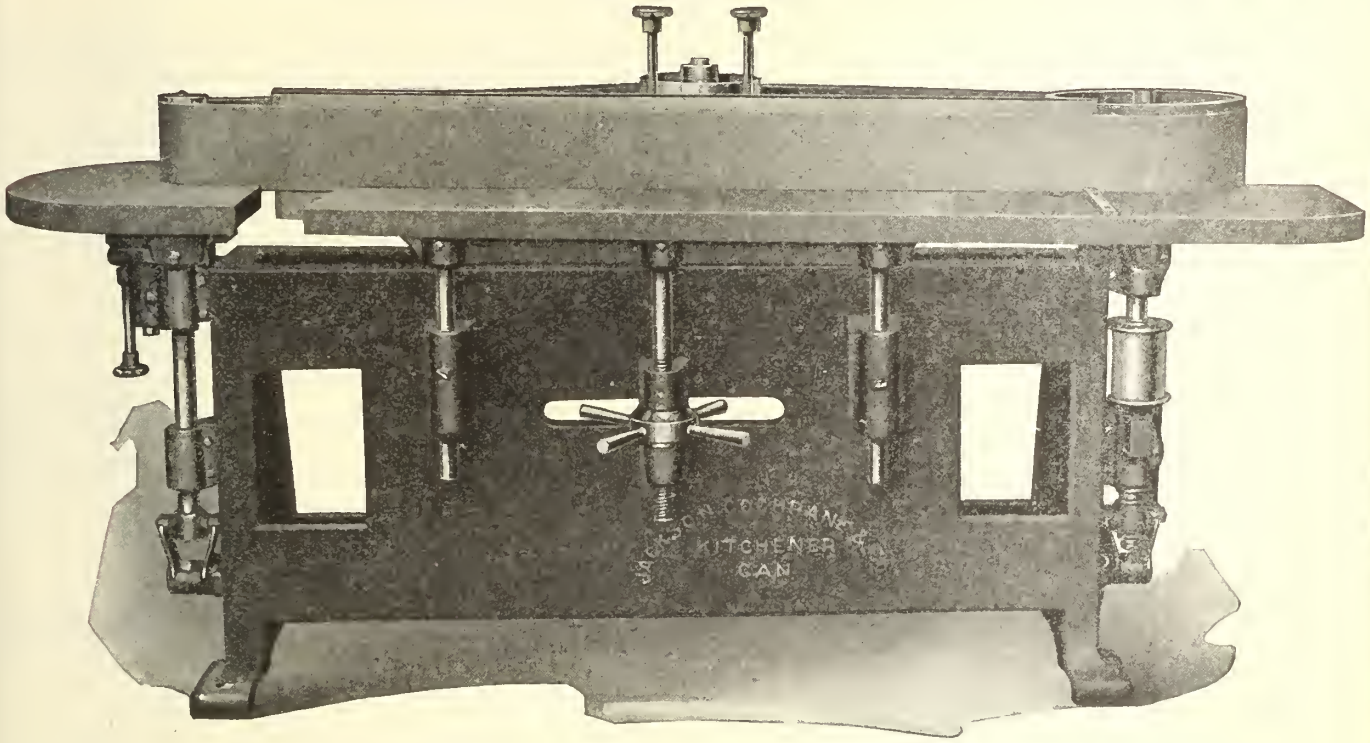
Capacity 30,000 to 40,000 lineal ft. per ten hours on 7/8 or 15/16 mop or sweeper handle stock.
If you are using any dowel machine of less capacity, figure your daily losses in labor and business.
Write us what dowel sizes you turn, and whether hard or soft wood. Ask for our demonstration proposition to show you how to double your production of dowel stock at the same labor cost.

The machine that is sent under a guarantee to show you a gain of from 100 to 400 per cent before you buy it.
The improved dowel machine that 90 per cent of the largest and oldest machinery builders and dealers now endorse and recommend in preference to the solid chuck machines they themselves previously built.
One cutter head turns from ¼-in. to 2-in. diameter.
Turns hard or soft wood equally well.
Handles heavy, oversized squares.
No choking of the cutter head.
Smooth stock.
Accurate sizes.
Works stock as short as five inches.
Rolls automatically center variations in squares.
Machines built to turn from ⅛ to 6-in.
We want to hear from every user of a solid chuck dowel machine.
We can save you from one dollar out of every two, to four out of every five that the operation of solid chuck machines costs you.
Engagements for competitive test solicited.
Formal orders not solicited. All sales made after demonstration.

The only question is, are you willing to cut cost of your dowel turning to one-half or one-third of what it costs with any make of solid chuck machine?
Machine delivers the goods before you buy.
State conditions of stock closely
Special conditions require special equipment.

W. S. Hawker Mfg. Company, Dayton, Ohio

No. 272 Oscillating Belt Sander



No. 272. Oscillating Belt Sander for Edged and Shaped Work

This style of belt sander has a capacity several times greater than sanding drums or spindles. The high speed sand belt covers a long surface and retains its sharp and fast cutting properties. The long travel of the belt gives it an opportuntiy to cool off between contacts, whereas on drums and spindles, where the sanding surface is small, the wear is continuous and in one place.

It will also finish practically any piece of straight or bent work that can be supported on the tables or held against the platen or sanding rolls.

The design and construction eliminates all chance of vibration, thus insuring a perfect sanding contact. The tables provide an even and accurate support for the work, and as the belt travels with an oscillating movement, a perfect finish is assured.

The tables are the proper height and permit the operator to handle his work in a natural position. Numerous sizes of sanding rolls, special forms for shaped work and non-revolving sanding spndles may be used for sanding a large variety of work. The long platen between the sanding pulleys may be removed and replaced with special forms for any work having rounded edges.

This sander is so constructed that a number of stationary forms may be used for special work.

Features of Our No. 272 Oscillating Belt Sander

Heavy construction eliminates vibration.

Long belt surface prolongs life of sand belt.

Oscillating movement prevents scratch marks.

Belt pulleys covered with heavy coating of rubber provide a good driving surface and a perfect sanding cushion.

Large tables and each adjusted independently of the other.

S.K.F. ball bearings in small belt pulley.

Improved belt tightening device.

Convenience of operation.

Large capacity.

Very moderate price.

Large descriptive circulars now ready. Send for one and get full particulars on this Sander.

Specifications:

Large Sand Belt Pulley.....14″ dia. x 8½″ face
Small Sand Belt Pulley.....3½″ dia. x 8½″ face
Circular Table.....25″ wide
11″ from spindle to end.
19″ long overall.

Long Table.....72″ x 12″
Platen.....60″ long 9½″ wide
Centre to centre of pulleys....72″
Idler Pulley.....10″ dia. x 9″ face

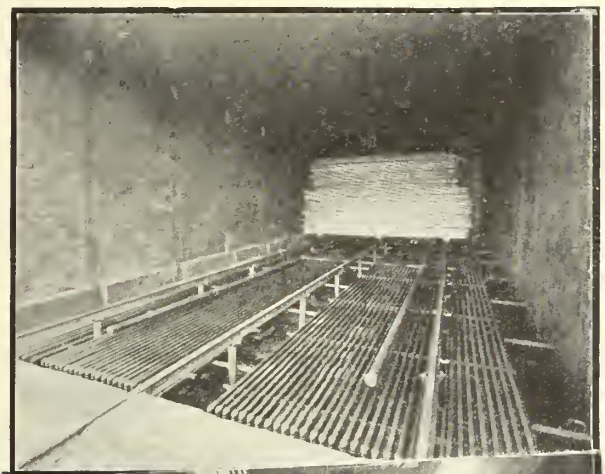
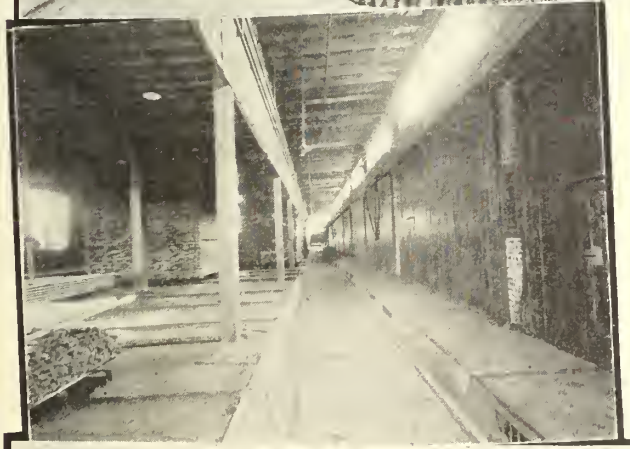
The American Seating Co. and the GRAND RAPIDS VAPOR KILN

The 3 photographs reproduced below were taken in the Grand Rapids plant of the American Seating Company and show typical kiln interior, transfer track and front battery of kilns and exterior view.
The American Seating Company has placed 3 orders with us—increasing their equipment as the Grand Rapids Vapor Kiln proved itself superior. Today they depend on a battery of 10 Grand Rapids Vapor Kilns to supply all their requirements for kiln dried stock.





We reproduce herewith 3 views of Grand Rapids Vapor Kiln installation at the new Grand Rapids, Michigan plant of the American Seating Company. This installation is merely typical—In Canada 250 units of the Grand Rapids Vapor Kiln are installed in over 83 progressive wood working plants, such as Weber Piano Co., Jacques Furniture Co., Kindel Bed Co., and Office Specialty Co. In a large percentage of these plants the Grand Rapids Vapor Kiln installation was made to supply new drying capacity but in a still greater percentage, these installations of Grand Rapids Vapor Kilns replaced other equipment that was proving too costly in the meantime, as well as unable to dry woods properly and economically. For safety, speed of drying and ideal results, there is no equipment equal to the Grand Rapids Vapor Kiln—the method and means for drying woods better in less time.

We maintain, as the very foundation of our continued leadership, America's most highly specialized and efficient laboratory service serving the woodworking industry. Technical bulletins covering practically every phase of wood curing problems are yours FREE upon request and the personal service of your corps of experts here and abroad is offered without placing you under the slightest obligation. Write for "Better Drying in Half the Time" today.

It's the cost of drying per board that counts

THE initial cost and the maintenance of your Kiln equipment, the time required to dry each load and the loss by degrade when the load comes out, must all be recorded in your cost of drying lumber. Cutler Kilns will cut that final figure, sometimes as much as in half for you, just as they are doing for many others today. Fewer kilns, quicker drying and practically no loss gives the Cutler method its lead over other drying methods.

So certain is this result that you owe it to yourself to investigate Cutler Kilns before spending another dollar on kiln equipment new or old. But you don't need to take our word for Cutler savings—we've put the opinions of a dozen Cutler users in a new little book called "Better Drying in Half the Time."

Send for your copy now and let these twelve men who know, tell you the facts. Our planning engineer will then go into your particular problem thoroughly with no obligation on your part.

Casco-made woodwork can be subjected to extreme variations in temperature and moisture without fear of separation.

The Casein Manufacturing Company

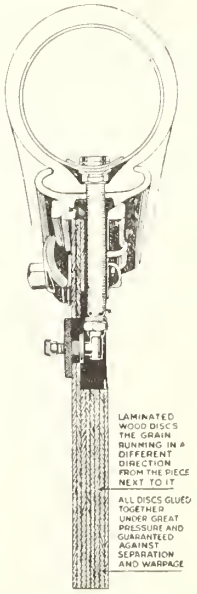
Largest and Longest Established Manufacturers of Casein Products in America : : :

15 PARK ROW, - NEW YORK CITY

Packard Single Six equipped with Dayton Discwood Wheels —and auto disc wheel of plywood, glued with Monite Waterproof Glue.

"DISC WOOD WHEELS"

Monite-Made



LAMINATED WOOD DISCS THE GRAIN RUNNING IN A DIFFERENT DIRECTION FROM THE PIECE NEXT TO IT
ALL DISCS GLUED TOGETHER UNDER GREAT PRESSURE AND GUARANTEED AGAINST SEPARATION AND WARPAGE

"We absolutely guarantee "Dayton Discwood" Wheels against warpage, separation or any imperfection, and we positively agree to replace any wheel broken under any condition if returned to our factory at Dayton, Ohio, for replacement."

The Dayton Automotive Wheel Co., Dayton, O.
(Signed) G. H. GORMAN, Pres.

That "Dayton Discwood" Wheels make good and stay glued is proved by the following quotations from a letter of Billy House, well known racing driver:

"While turning the one-half mile track in 31 seconds she struck a slight wave at the south turn, the result, she jumped the eight-foot embankment, volplaned about forty feet and struck another bank nose on, cut the top of the bank and made a slide of about twenty feet and stopped right side up, no one badly hurt.

"Now for the mystery part of the Dayton Discwood Wheels. After twisting the axle to look very much like a corkscrew, cracking a nickel steel spindle half through, plowing the top of the bank, plus the drop of eight feet at the rate of nearly sixty miles per hour, the inside lamination slightly cracked. We put in new spindles, changed sides and let them ride, and ride they did, they finished the season in grand shape. Every time I look at the wheels, I say to myself, 'If you had been any other than Discwood we would have had a double funeral.'" (Signed) BILLY HOUSE.

Manufacturers who make glued products; dealers who sell, or people who use them, are learning to ask for and expect the service and durability that only **Monite Waterproof Glue** can give.

To give you a clear idea of what MONITE will do, send for our small vest pocket panel of plywood made with Monite Waterproof Glue. Boil, Bake, soak or freeze it—**Monite Sticks to Its Job.**

Samples and circulars on request.

CLAMP NAIL COMPANY

4532 Palmer St. **CHICAGO, U.S.A.**

Quality *from the source*

Thirty Years Ago,

Chapman and Dewey Lumber Company purchased 100,000 acres of Hardwood Timber lands in St. Francis and Poinsette Counties, Arkansas. The selection of this Timber Tract was made after a careful study of Hardwood Stumpage in the South, and the purchase made there primarily, because of the exceptional **Quality** of the Hardwoods growing in this St. Francis Basin. Since that day thirty years ago, St. Francis Basin Hardwoods have acquired a national reputation. Discriminating buyers realize that lumber from this stumpage cannot be excelled for the most exacting requirements of fine wood working.

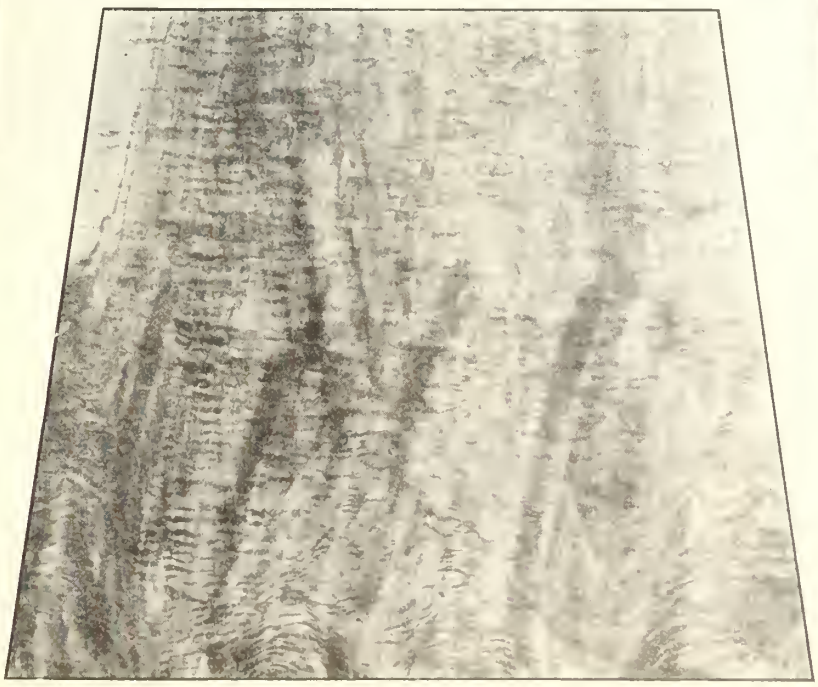
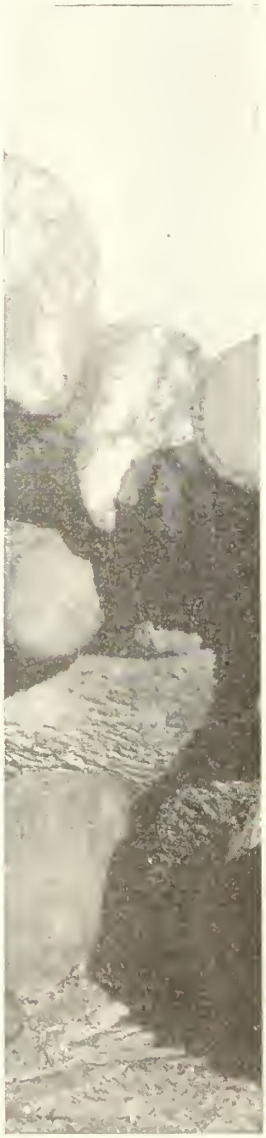
Walnut?—Yes,—Good Walnut?—Yes!
Pickrel

Walnut's sheer beauty, strength, uniformity and permanence brought it in a few years to unquestioned supremacy in furniture construction. Dominance in furniture proves but the beginning. This surpassing merit is every day compelling increased use in new cabinet fields. Pickrel walnut veneers fill an important place in this wider development. A limitless selection of quality veneer logs, careful and skilled manufacture and a constant stock of five million to seven million feet of nicely assorted woods have given Pickrel walnut veneers a special significance. Buyers will appreciate the responsible, conscientious and experienced representation through which Pickrel veneers are offered at their respective plants. It assures the closest possible conformity to the individual requirements of each—meaning less cost in working and a better product.

PICKREL VENEER CO.

New Albany, Indiana





"Better Use Birch"

The Utility of Birch

Marvellously figured, satin textured, close grained and HARD! Birch is coming into its own. The rare beauty and utility of this wood lend themselves admirably to the cabinet-makers' art. Nature builds birch slowly in the tree—and the close knit fibres form a wonderful base for enamel, holding it permanently and resisting dents. The light, natural color also permits of a vast range of stains and finishes. For panels and veneers, Curly Birch is supremely beautiful.

Yet withal Birch is inexpensive, economical and enduring.

The chair illustrated above is a typical example of the beautiful creations being manufactured from Birch.

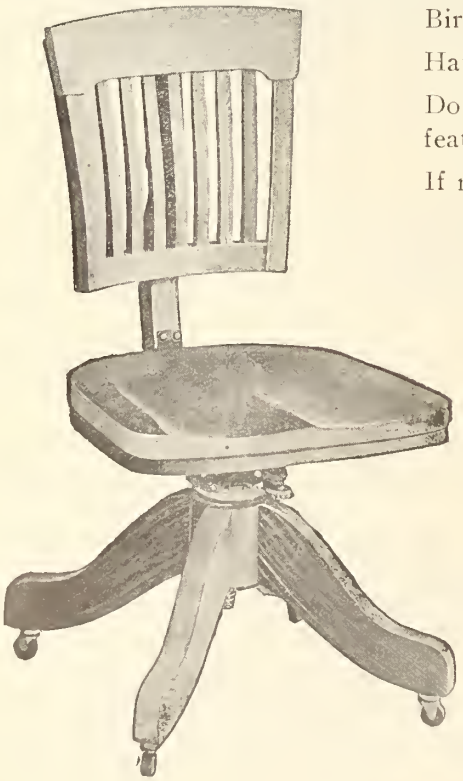
Business Needs this type of Furniture

The type of office furniture that immediately creates an "impression" upon the customer or visitor; that is able to withstand the day after day grind and look as good at the end of a year as the day it was bought; that lightens labor and speeds up work—that is the kind of furniture business needs.

In other words, business needs furniture that is economical, efficient and attractive.

And those are just the qualities that a large American manufacturer of office furniture—a client of ours—is building into his products—with the aid of Canadian Birch, supplied by Edward Clark & Sons Ltd.



Have you investigated this super-hardwood yet?

Do you know of its may superior features—features that mean real business for you?

If not let us forward you a few facts.

We have available for immediate shipment a quantity of dry 4/4 Birch, No. 1 and 2 Common. Try a carload. Satisfaction guaranteed.

MAHOGANY

Rarely are such stores of precious wood to be found as may be seen in our yards. Across the seas from tropic lands it comes. From thick jungles where the light of day but dimly penetrates and where tangled native paths make difficult the bringing out of timber. Here the black man labors, risking life from jungle dangers, that supplies will not diminish and your orders may be filled.

Twelve million feet per year is the capacity of OTIS mills. An adequate supply is always on hand for prompt shipment. Get our prices.

Production Decreased by Unhealthy Shop Conditions

Woodworking has been regarded generally as relatively free from those disagreeable and devitalizing diseases that seem to be so inseparably associated with many other industrial occupations. The mining, the iron and steel and the packing industries, for example, have been considered to involve hazards from a disease point of view that are of more or less harmful proportions, depending on the degree to which the workers are exposed to them. That it is possible for these so-called occupational diseases to be serious in the extreme is well illustrated by the fear with which, not many years ago, workers labored in the match factories. There, certain operations, involving the use of poisonous chemicals, so undermined the physique and vitiated the blood that death crept slowly but surely upon the unfortunate toiler whose lot it was to earn his living under these circumstances. Today such conditions are rarely met with, thanks to the power and advance of industrial hygiene which is constantly seeking to alleviate the sickness hazards that surround industrial occupations. And yet, in many industries and in many individual plants, workers are being unnecessarily subjected to such disease-inducing and health-undermining surroundings that they are as slowly but as surely dying as did the match workers of a few years ago, with this exception only that those match workers knew beforehand the fate that awaited them while today's toilers are generally unaware of the hazards or being aware of them, do not expect them to be of serious consequence. However, the statistics, which many investigators have compiled, relating to industries in which occupational diseases are known to be prevalent, show just how very disastrous and serious they are, not alone in actual sickness but also in the diminished capacity for work among those exposed to the hazards and in the consequent loss of production.

Woodworking, while certainly not one of the most hazardous industries from this point of view, is, nevertheless, fraught with certain dangers that make it well for operators and managers to analyze the conditions under which their plants are operating. To show the hazards to which woodworkers are exposed, an article by J. F. Rogers, written at the editor's request, is published elsewhere in this issue. It is a concise yet thorough consideration of the problem of health in the woodworking industry. It is hoped that more will be printed on this topic so that proper emphasis may be given to a matter that has a very serious effect on production. Indeed, there is a possibility that government bodies in Canada will endeavor to investigate thoroughly, the whole industry from an occupational disease standpoint. If such an official investigation develops it is hoped that the operators of woodworking plants will render every possible assistance in the matter of gathering figures and statistics, of which at the present time there are all too few.

An Analysis of Costs in the Millwork Industry

Most of the readers of the "Canadian Woodworker" will be much interested in the chart which appears on page 55 of this issue. It represents a graphic analysis of costs prepared by the Millwork Cost Bureau of Chicago, that organization that is doing such excellent work in putting cost-keeping and estimating in the woodworking industry on a substantial basis. This Bureau has undoubtedly gone to a great deal of trouble to collect and compile the figures that form the basis of the diagram referred to, but the results will be worth while if millmen will take the opportunity of studying the contents of the diagram and the explanatory comment which accompanies it. While the chart as reproduced in the "Canadian Woodworker," was somewhat amended from its original form, for reproduction purposes, copies of it in the shape gotten out by the Millwork Cost Bureau may be obtained from that organization gratis. This offer is extended to any millwork organization irrespective of whether they are members of the Bureau or not. Incidentally, the fact that the service is not confined to members only shows a splendid spirit of co-operation and service to the whole woodworking industry.

It is not the intention of this comment to trespass on the lengthier article that appears in connection with the chart, but just to emphasize its importance and draw our readers' attention to it. Briefly it represents an analysis of the operating costs of 13 representative millwork plants. Their material, labor and burden factors are all indicated in terms of dollars and also percentages. In each instance the figures were taken from reports of actual cost surveys conducted by Bureau accountants, and hence whatever was material, labor or burden in one establishment is material, labor or burden in each. The chart graphically portrays the fact that no two plants operate similarly and that, therefore, there is considerable variation in the proportions of the three basic cost factors. How the nature of the business carried out by each plant affects the proportion of these factors is carefully explained in the article. One of the impressive points of the analysis is that the 13 firms show an aggregate burden equivalent to 29% of the total cost which is much more than the average labor factor of all plants, or, for that matter, of any indi-

vidual plant. Incidentally, we emphasize the importance of the burden factor and urge that it be determined on a proper basis. In this connection the Millwork Cost Bureau's standard plan of burden calculation seems the only correct and logical medium for burden expression.

In analyzing the chart our readers are reminded that the rates shown must not be considered as representative of the industry as a whole. They are simply individual experiences.

Nine Rules for Material Handling

Nine rules that apply to material handling problems and the selection of material handling equipment are given by W. T. Spivey in Factory. (1) Know every kind of equipment on the market. A haphazard selection of equipment which will do the job only reasonably well is a poor investment in the long run. (2) Analyze material routing carefully. The relation between the elements in a material handling system is, in many cases, more important than the design of the equipment itself. (3) Visualize the job's actual needs. No, two plants have exactly the same problem. While the same principles apply in most cases, careful study of individual requirements pays well. (4) Buy for an operating saving, not for first cost. The man who buys on price alone doesn't always get what he thinks he does. Correct engineering analysis, a good machine, and subsequent service are worth a fair price. (5) Get together with the designer and the manufacturer. Doubtless there is much equipment manufactured which is not ordinarily known. How to select the best machine adopted to particular needs is a matter of engineering judgment gained through the experience of successful installations in other plants. (6) Lay out the equipment when the building is planned. A building is best planned with both eyes on economical manufacturing. Material conveying machines are the links which join other machines into unit production. (7) Re-arrange equipment systematically. A different product or a different operation sometimes requires an entirely different application of the machine. Many a "patch-work" job has been done without thoughtful planning. (Teach the operator the possibilities of his equipment. The science of material handling is a new one. Like the lathe, drill press, or milling machine operator, the man who runs the conveying machine will do a more effective job if he knows what it is all about. (9) Maintain conveyors as carefully as production machinery . Lift trucks, gravity conveyors, tiering machines, and so forth, are more than mere wheel-barrows. Each represents an investment and a heavy depreciation makes the investment a poor one.

Co-Operation—Putting a Little in and Getting a Lot Out

A ragged and dejected stranger was observed one day walking down the middle of the main street of a bedraggled village. He looked neither to the right nor to the left, but kept his eyes on the road in front of him.

When he arrived at what seemed the biggest section, he stooped down and picked up a stone, examined it carefully and with a wild cry of delight threw his tattered hat into the air and danced around with great glee.

A crowd gathered and the vagabond was asked the cause for his jubilation. "Cause enough," he replied, "this,"—holding up the stone that all might see it—"is the great soup stone for which I have been searching all over the world." And again he gave vent to his paroxysm of joy. The onlookers were now very curious and the tramp was forced by many questions to explain what the stone was good for.

He quickly called for a kettle of water that he might demonstrate the wonderful power of the soup stone. A great copper kettle was produced and somebody brought the wood for a fire and someone else brought the water. The fire was soon made and the water boiling.

Then, in hushed expectancy, the stone was tossed in. As the bubbles rushed to the top the stranger pointed to the grocery store and said: "It would make it better if we had that head of cabbage"—and as it was produced—"That's right, throw it in." A farmer's wagon stood nearby with a carrot or two visible on the bed. "There's a carrot—say! just hand that over—and—Can't you get a bone from the butcher?"

So it went. The pot boiled merrily and the stranger under the excitement of the moment got first one ingredient and then another until a fine kettle of soup was done. Then dippers were procured and everybody was given a generous helping.

But a canny old farmer, after tasting of the soup, said: "Why, this fellow is a fake. That stone he found ain't got nothin' to do with the soup. Everything he put in it we furnished."

Turning to the skeptic, the stranger said: "My good man, what did you put into the soup?"

The farmer replied, "Why, that's my wagon over yonder that you got the carrot out of."

"Well! Well!" rejoined our friend, "you put in a carrot and you get back a bowl of soup—your little donation brings you a share of what everybody else contributed. You put in a little and you get back much. That is co-operation."

The Effects of Good Lighting

A factory illumination authority has said that a factory whose lighting equipment has not been relamped within the past five years, is obsolete. In connection with lighting, the factory manager must consider three things: the window illumination, the electric units for artificial lighting and the factory decoration. The effects of good lighting, of bright and cheery surroundings in the work room includes:

1. Better working conditions,
2. Increased production,
3. Greater accuracy in workmanship,
4. Less spoilage,
5. Reduced bills for lighting,
6. Neatness and Sanitation of plant,
7. Less eye-strain,
8. Reduction of accidents,
9. Improved morale among employees,
10. Reduction in labor turnover.

If one neglects one of the three essentials, the chance of securing all the ten resultants, are greatly reduced.

The Pulitzer interests of the New York World, which own the controlling interest in the pulp mill in St. George, N. B., are understood to be contemplating the erection of a woodworking mill adjacent to the pulp mill if it can be shown that the cost of power from the Musquash hydro station will be cheap.

Is Woodworking a Healthy Occupation?

The Dust Developed During Woodworking Operations Has a Serious Effect on the Workers and by Decreasing Their Physical Powers Reacts on Their Productiveness—How to Combat Occupational Diseases

By James F. Rogers*

Workers with wood, from those who fell trees to those who produce finished products of all kinds, are very subject to accidents from machinery, from flying pieces of wood and from edge tools. The woodworker has, however, been looked upon as relatively free from disease attributable to his occupation and at first glance the seeming cleanliness of his work would tend to allay suspicion. Many of the processes are, however, dusty and while wood dust is certainly not so injurious as that from some other materials, its inhalation is not a normal, physiological process and the presence of this foreign substance in large amount might be expected to have some deleterious effect upon the respiratory organs. Dust from hardwoods, on account of its smaller size and its hardness, is relatively more irritating. Rattan contains a considerable amount of silicious material and silica dust has, for a long time, been known to be highly injurious to the lungs, and where sandpaper or sanding belts are used silica always forms a part of the dust breathed by the worker. As illustrative of the irritative effects of this mixture of organic and inorganic dusts, R. Prosser White, (Occupational Affections of the Skin, 1920, page 101) says: "Sandpapering hardwoods, e.g., ash, in wood turning shops fills the room with fine dust. After a holiday both new and old hands experience all the symptoms of coryza, for the first two or three weeks, from the hard particles irritating the eyes, nose and throat."

Extent of Sickness Among Woodworkers

In a study of 5,341 cases of illness among 10,171 wood-workers in Vienna in 1904 Sternberg (Weyl's Handbuch der Arbeiterkrankheiten, 1908, page 432) found that 28.1 per cent were suffering from tuberculosis or some other form of disease of the respiratory organs, and according to Roth (Gewerbekrankheiten, Berlin, 1909, page 190) 61.7 per cent of all the deaths among wood turners in Berlin for seven years were caused by consumption. A high percentage of sickness was found among wood-workers of Alsace, and Neisser in a wooden tool factory in Strassberg found that fifteen out of twenty workmen were sick during one year (1904), chiefly from respiratory diseases, with a total loss of 288 days from work. Neisser, Internat. "Ubersicht u." Gewerbehyg., 1907, page 115).

Sir Thomas Oliver (Dangerous Trades, page 135) has pointed out that the mortality from tuberculosis and from other respiratory diseases among coopers and wood turners of Great Britian was more than duble that for agricultural workers.

Robinson and Wilson of the U. S. Public Health Service (Public Health Bulletin No. 73, 1916) examined two hundred and seventy-three wood-workers in three factories in Cincinnati, the greater part of the men being coopers and bung makers. Seven cases of tuberculosis were found with a percentage of 2.56. These factories had installed blowers but they "were not always successful in eliminating the dust." No thorough going study of the subject, such as it deserves, has as yet been made in this country.

While the dust from most woods probably acts as a mechanical irritant, that from some of the less common woods produces definite symptoms of poisoning. According to Oliver (Dangerous Trades, page 791) workers with Sequoia wood may suffer from symptoms of an acute cold in the head and may even have difficulty in breathing and a sense of oppression in the region of the stomach. "A kind of tolerance comes in time to be established, although in cases of men who are subjects of asthma and throat affections their experience is painful and the effects enduring." The following woods are said to have an irritating effect upon the skin: African ebony, magenta rosewood, West Indian boxwood, cocus wood, partridge wood, olive wood, Mexican blue gum and teak wood. Thompson (Occupational Diseases, page 448) says that the dust from teak wood "may give rise to nausea, vomiting and other constitutional symptoms," while that from boxwood may cause "depression of the heart and general muscular weakness."

In woodworking factories the continuous noise from saws and planing machines has a disastrous effect upon the hearing of the men, the workers about drying kilns are subject to high temperatures and in the finishing of woodwork with bleaches, stains and polishes the workers are often exposed to highly poisonous substances. As these latter processes do not belong to woodworking proper they will not be discussed here.

Dust the Outstanding Menace

Dust is evidently the outstanding menace to health of the wood-worker, and, from the figures quoted from the foreign investigators, it is of serious consequence. Along with actual disease there must be also diminished capacity for work among many who do not show definite symptoms. This reduced capacity for work as well as the possible development of disease from this cause should lead the factory manager to install effective means of removing dust.

Aside from any specific conditions of the trade which may be harmful to the health of the worker, the ventilation, lighting, seating, water supplies, sanitary arrangements, and not least, the mental and physical fitness for the job deserve to be looked into, for all these things make for the well-being of the worker and react on his productiveness.

A thorough physical and mental examination should be given at entrance, and at regular intervals and the man placed in the job for which he is mentally and physically best adapted. The keeping of accurate sickness records may be a help in tracing the effect of work and conditions of work. While we are taking great pains to prevent cuts and bruises and broken bones, it will pay to prevent the more insidious and usually more serious accident of disease which reduces capacity for present work and shortens the time of future usefulness.

*Acting Assistant Surgeon, U.S. Public Health Service.

How Are Millwork Costs Distributed?

A Graphic Analysis of the Operations of Thirteen Plants Shows Considerable Variation in the Proportions of the Three Basic Cost Factors, Material, Labor and Burden—What Such an Analysis Teaches

By the Millwork Cost Bureau, Chicago

Millwork operators frequently inquire, "What portion of my annual costs should be labor," or, "Considering a year's operation, what are the proper percentages of material, labor and overhead that make up the total cost of an average millwork plant?, etc., etc.

No one familiar with the cost problem of the millwork industry would attempt to answer such a query, because in this trade there exists no standard of comparison of the kind mentioned. Just what is an "average millwork plant?" Is it the one that occupies the position of a necessary evil in the transactions of some retail yard? Would it be the plant that manufactures its entire line of merchandise and does no jobbing to speak of, or is it the establishment that tries to job everything and manufactures only what it must? Then there are also what are strictly sash and door mills producing nothing but stock items, veneered door specialists manufacturing both stock and special work, trim and flooring factories, frame shops, stair builders, cabinet makers, and column manufacturers. All fall under the nomenclature of millwork—they are similar in many respects and dissimilar in just as many more. Their physical properties, land, buildings, equipment, and layout are vastly different. At the present time, wage rates range from 30 cents an hour in one market to something in excess of $1.00 an hour in another. The kinds and grades of lumber that predominate in this or that institution are just as variable. Viewing the situation in that light leads one to conclude that an "average millwork plant" is non-existent.

The accompanying graphic chart portrays this lack of operating similarity and subsequent variation in the proportions of the three basic cost factors —material, labor, and burden (or overhead)—in most forceful fashion. None of the thirteen firms charted was selected for analysis because of its physical properties, but it was attempted to make the chart geographically representative, and therefore no two plants in the same city, or, where it was possible, in the same state, were used. Aside from that there was no discrimination. The cost figures in each instance were taken from the reports of actual cost surveys conducted by Bureau accountants; hence they are uniformly arrived at, and whatever was material, labor, or burden in one establishment, is material, labor, or burden in each. Because of the large sums involved, it was necessary to depict all costs in round numbers, but in every other respect the chart conforms to the actual figures.

Significance of "Material" and "Labor"

The term "material" signifies direct material; that is, such material as may be traced directly to this or that job or order. Brads, screws, etc., are considered Bench Burden, unless used on power-driven machinery, in which case they would be classed Machine Burden. There are some materials which, while they may be traced directly to a specific order, would by so doing involve lengthy or cumbersome calculations, for which reason they are placed in the "indirect" class and become a portion of the factory burdens. Direct material is divided into two groups; viz., lumber, which requires no explanation, and other direct material, which is composed of such items as glass, mirrors, veneers, hardware, and any millwork purchased outside, whether it be fully assembled or in various uncompleted stages of fabrication. In case a retail yard is operated in connection with the mill, such items as flooring, roofing, building papers, and the like, are grouped with Other Direct Material, and the rough lumber—boards, dimensions, timbers, etc. —for burden purposes, is grouped with the factory lumber.

By "Labor" is meant direct or productive Labor. Like direct material it consists only of such costs as are occasioned by a specific order. Supervision, equipment or building repair labor, trucking (both motor and hand-power), powerhouse labor unloading labor, delivery, shipping and warehouse labor, selling, billing, etc., are all Indirect—it is impossible or impractical to charge them against a given job; hence they are distributed to one of the burden units.

What is Involved in Burden

All cost or expense that is neither Direct Labor nor Direct Material by that token is Burden. The M.C.B. Burden Plan involves five distinct rates; to wit:

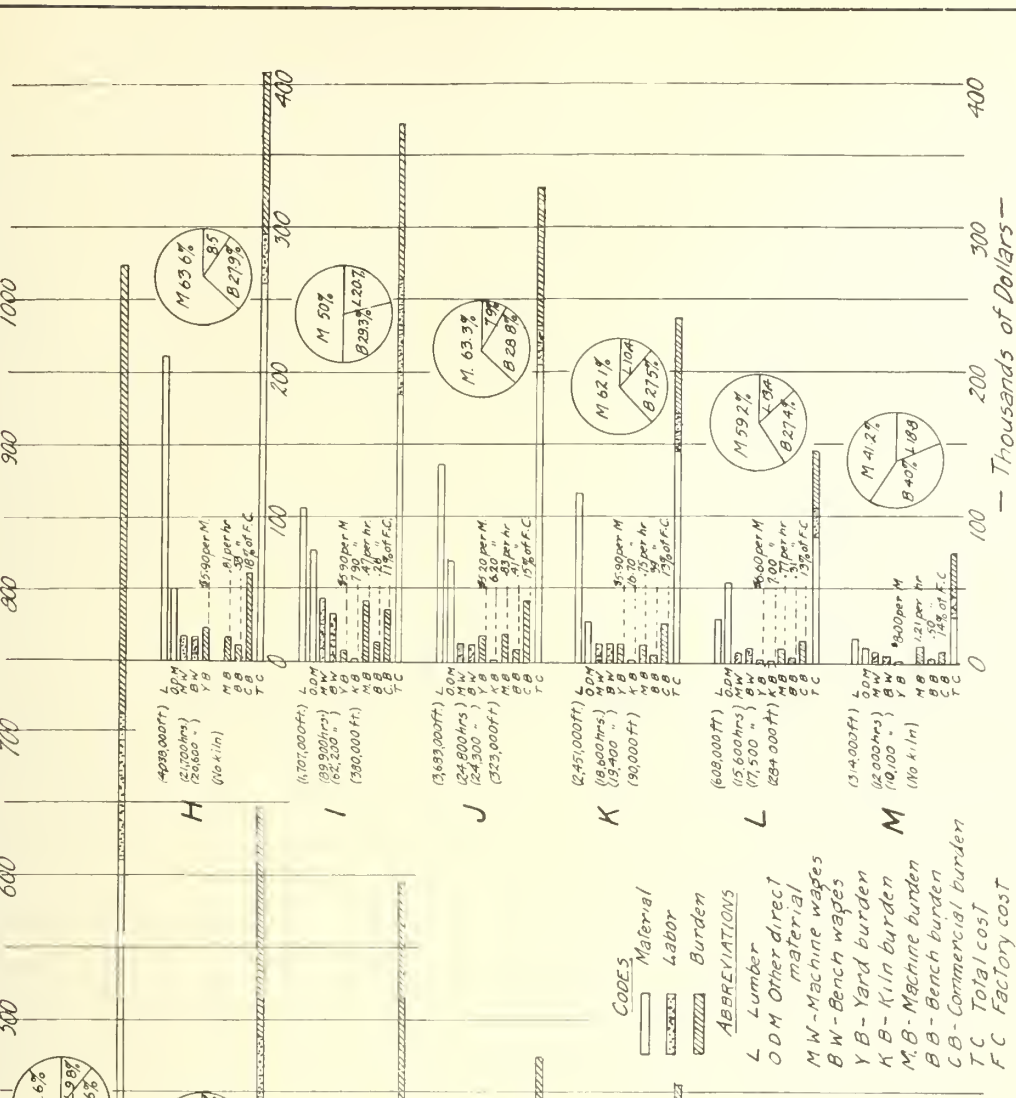
1. **Yard Burden,** which embraces all cost of handling and carrying lumber from the moment of its receipt until entry to the mill or, if not worked, until taken over by the delivery crew. This burden is expressed as a flat rate (dollars and cents) per thousand board feet consumed.

2. **Kiln Burden,** which is composed of all cost incident to drying in the kilns. It is expressed as a flat rate (dollars and cents) per thousand board feet dried.

3. **Machine Burden** is all cost—exclusive of direct workmen's wages—of operating the machine equipment and housing it and the workmen. It is expressed as a flat rate per direct man-hour.

4. **Bench Burden** is all cost—exclusive of direct workmen's wages—of operating the bench department and housing the equipment and workmen. It also is expressed as a flat rate per direct man-hour. Where a crew of painters and finishers are steadily employed for filling, staining, shellacing, etc., a Finishing Burden per direct man-hour should be established. However, in the absence of a sufficient volume of such work, finishing is considered simply as bench work.

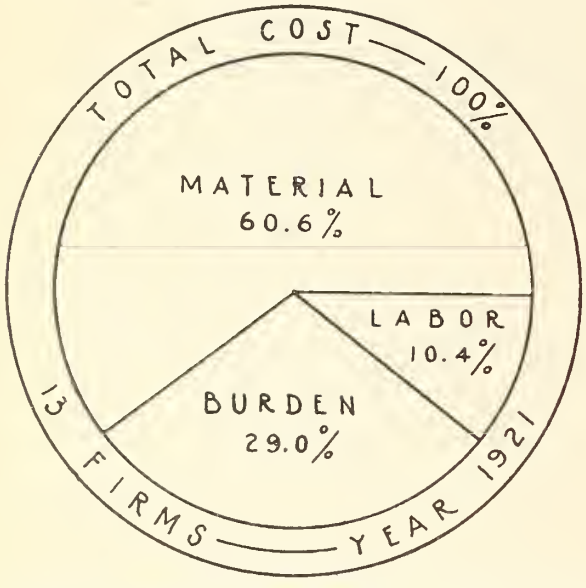
5. **Commercial Burden** is all cost occurring after the manufacturing processes have been completed; that is, all warehousing, delivery (no outgoing freight), selling, general office, and administrative expenses. Commercial Burden is expressed as a percentage of **Factory Cost,** which is Direct Material plus Yard and Kiln Burdens, Plus Direct Labor, plus Labor Burdens.



Comparative analysis of cost complied by the Millwork Cost Bureau from the reports of Bureau accountants to thirteen member-firms, each of which had undergone the processs of a cost survey and installation of the standard cost finding system. Complete copies of the chart will be supplied gratis to any millwork operators by the Millwork Cost Bureau

Explanation of the Chart

Throughout the chart, where the terms Material and Labor occur, they signify **Direct** Material and **Direct** Labor. All other terms, symbols, etc., occurring on the chart are self-explanatory. Observe that each firm's total cost for the year is illustrated graphically in three ways, first, by rectangular graduations representing dollar values for each component unit of material, labor, and burden, second, these component units or sub-factors are combined into their three main factors—material, labor, and burden —and likewise are charted in rectangular graduations for dollars expended; third, each firm's annual total cost is depicted by means of a circle with segmental divisions indicative of the per cents of material, labor, and burden constituting the whole or 100%. The board feet of lumber consumed and the board feet kiln dried are shown in parentheses in the left-hand margin of the chart, as are also the number each of Direct Machine and Direct Bench Hours. This information is included for the purpose of describing more specifically the nature of each firm's business.



The proportions of material, labor and burden in the millwork operation of the thirteen firms

The burden factor of each plant has also been converted to rates in accordance with the standard M.C.B. practice outlined earlier in this review. These rates appear to the right of the unit burden delineations. **They more than any other medium express the precise cost status.**

Firm "A", with a consumption of nearly 5,000,000 board feet of lumber and $375,000 worth of Other Direct Material, it is apparent conducts an extensive retail yard and jobbing business in addition to its manufacturing operations.

Firm "B", also indulges heavily in jobbing, as is evident from the extent of the Other Direct Material. This plant used, in dollars, almost the same amount of lumber as "A", but the feetage is approximately 1,000,000 feet less. Its predominating lumber was therefore of a higher grade and value than "A's", even though "A", as may be seen by a comparison of the Direct Labor Hours, did considerably more manufacturing than "B". Note that "A's" Yard Burden is about $6,000 lower than "B's" and that "B's" kiln operation was more costly than "A's". "B's" totals in both instances involved much less feetage, which is evidence that "A" operated nearer maximum capacity than "B", or that "B's" equipment is at fault. The fact that "B's" Machine Burden is equivalent to 93 cents per man-hour and "A's" only 51 cents, bears out this contention. "A" it may be observed produced more cabinet than machine work, whereas with "B" the production was largely trim, etc.

Burden in the Various Plants

The highest composite burden of any one plant expressed as a percentage of total cost is 40% in the case of Firm "M" (refer to the segment in "M's" circle marked "b"; that is Burden). Firm "D" experienced the lowest aggregate burden: viz., 22.2% of total cost. However, it is interesting to note that Firm "D's" Factory Burden rates—Machine and Bench—are in nowise low; in fact they rank among the very highest. Its redeeming feature, or the one responsible for the low level of its total burden, lies in having disposed of much jobbing stock at a very economical operation of the warehouse and office units. Commercial Burden in this case amounts to only 8% of Factory cost. That is perhaps the lowest rate developed since 1914.

Observe the excessive Commercial Burden occasioned in the operation of plant "F". Ordinarily, a jobbing business—which is essentially what this was —tends to diminish the rate of Commercial Burden, but in this instance the rule miscarried. This particular exception to the rule may be due to jobbing large quantities of materials of low value and employing too costly warehousing and sales facilities for their carrying and disposal. Then again it may be attributable to that not uncommon post-war condition—a radical decrease in the value of stocks consumed, without a corresponding reduction in commercial expense. Firm "F", as has been indicated, engaged in manufacturing in only a limited way, which fact is responsible for its high factory burdens. Comparatively, it appears that the yard site is too extensive or too valuable for its milling department; otherwise why should the rate of Yard Burden be the imposing sum of $15.40 for every thousand feet of lumber consumed?

Compare the total costs of Firm "F" and "G". For all practical purposes they are identical. Little differences exist in their gross burdens. "F's" total material exceeded "G's" by approximately $25,000 which, however, is not a momentous difference. Why then is "G's" total Commercial Burden and its per cent rate so much less than "F's"? The answer is, Firm "G" directed its energies towards a voluminous consumption of lumber, amounting to about 2,250,000 feet more than "F's". Plant "G", as is evident from the Machine Wage and Machine Burden units, indulged rather extensively in certain fabricating processes, such as box construction with power-driven equipment, or a trim operation involving a low-priced wood. In either event the material turnover was rapid and the carrying cost small. "F's" Other Direct Material consumption required extensive warehousing facilities, whereas "G's" lumber turnover, which was its heaviest unit, entailed only the use of a yard and sheds.

This review could be carried on almost interminably along the lines followed in the preceding discussion, but inasmuch as the chart is so very complete it will be the reviewer's purpose to refrain from further comment of that nature. The reader, however, should continue the scrutiny and establish additional conclusions. The impressive points of this analysis are first, that the thirteen firms show an

aggregate burden equivalent to 29% of total cost, which is much more than the average labor factor of all plants or, for that matter, of any individual plant. It should be pointed out also that the segments representative of the per cents of total burden are much lower than if they were expressed as a per cent of material and labor combined. A burden given as 25% of total cost is equivalent to 33-1/3% of material plus labor cost. The second point which must impress one is that the M.C.B.'s standard plan of burden derermination; viz., Yard and Kiln Burdens at a rate per thousand board feet, Factory Burdens at a rate per man-hour, and Commercial Burden at a per cent rate of Factory Cost, constitutes the only correct and logical medium for burden experssion. the circles with segmental proportions are resorted to merely for analytical purposes, and whenever used should be accompanied by unit rates as in this instance. The rates shown on the chart should not be considered representative of the industry nor of the Bureau membership. They are simply individual experiences.

Furniture Business Active

The New York Exposition Was Remarkably Successful—Record Number of Sales

The New York furniture exposition opened on October 16th in the new permanent home of the New York Furniture Exchange, with the largest first day's attendance ever recorded at any exposition. There was a total of 449 buyers registered on the first day of which 400 were from eleven eastern states. Up to the present writing the total attendance for the two weeks of the exposition numbers 2,812 which is a record breaker.

The volume of business written also exceeded any previous business, even during the days when everybody rushed pell mell to buy merchandise, but the difference was in the fact that the dealers used judgment and discretion and did not overbuy as they did three years ago. It was unfortunate, however, that a great many of the manufacturers had an immense volume of business on hand, and owing to the great demand, many of them were compelled to hang out "sold up" signs after the third or fourth day of the market season, but fully sixty per cent of the manufacturers continued to take orders until the close of the show, promising to do the best they could to fill orders.

Prices range from ten to twenty per cent higher than last April according to the grade of merchandise. Bedroom suites which contain mirrors were advanced more than furniture that did not contain mirrors due to the rapid advances in the price of mirrors which show an increase of over 50% in the past four months, and what has made it worse has been the inability to secure the mirrors even at the increase in price.

It can be truthfully said that this has been the most successful of all previous expositions, both in number of attendance and in volume of business that was written.

Edward Clark Passes Away

The passing of Edward Clark, father of A. E. Clark, Toronto, president of the Canadian Lumbermen's Association, removes a veteran figure in the lumber industry. Mr. Clark who was seventy-five years of age, died at the residence of his brother, Rev. Dr. George Clark, St. Catharines, Ont., on November 12th, after a long period of poor health. He was born in Hull, England, and came to Canada when six years of age, locating with his parents at Dundas, Ont., and later in Binbrook township. When Mr. Clark first started out for himself he lived in Forest and later in Bridgen where in addition to conducting a farm, he operated a sawmill. During his residence in Bridgen he bought blocks of timber from the neighboring farmers and conducted an extensive rural lumber trade. Eventually disposing of his mill and other interests he embarked in the wholesale lumber business in Hamilton, Ont., where he remained until 1907 when he came to Toronto. The firm was first known as Edward Clark, then as Edward Clark & Sons and later as Edward Clark & Sons, Limited. It has been conducting a large wholesale trade in birch and other hardwoods and has extensive connections all over Canada and the United States.

The funeral took place on November 14 from the residence of his son, A. E. Clark, every branch of the forest products industry being well represented at the service. A large number of beautiful floral tributes were sent by friends and organizations with which he was connected.

Accurate Cost Accounting

The importance of accurate cost information in dull times is emphasized by William R. Basset in the American Machinist. A delusive cost system is much worse than none at all. Most home-made systems are delusive. They do not take enough factors into consideration.

The common method for getting at sales expense is to divide the total of merchandise by the total of sales expense. The figure thus obtained is supposed to be the percentage cost per dollar of sales. This is true only if all the goods are exactly alike, priced alike and sold under the same conditions. What really results is the loading of high-priced articles with such a volume of sales expense as to make their movement difficult and to relieve low-priced articles of so much sales expense that actually they are often sold at a loss.

The subject of units of sale is one which deserves a great deal of attention from business men. The unit must be determined by the costs and when that unit is once determined, variations from it have to be sold at prices dictated by the relative cost.

Sales costs are rarely accurate and manufacturing costs are in but little better condition. One of the many fallacious ways of estimating a manufacturing cost is to compare the labor and overhead with the cost of the material. This method can hardly give a figure that means anything because the value of the material is only a factor entering into the cost of the finished product. The value itself in no way determines the amount of work that has to be put on the material or the space it occupies.

Simplicity is the keynote of modern cost accounting. But the simplifications have to be scientific.

Driscoll's factory in West St. John, N. B., has been working on dressed lumber through the summer and early fall. The expectation is that this plant will be operated through the major portion of the winter as usual.

Check Up the Circulation in Your Dry Kiln

Uniform Air Movement is the Important Factor in Successful Drying—If the Kiln Depends on Natural Circulation, Provision Must be Made for Controlling and Directing it if Drying is not to be Prolonged and Cost Increased

By F. P. Poole*

Circulation, that is, adequate, uniform circulation, is probably the most important factor in the successfull drying of lumber by artificial means. There are other necessary factors such as heat and humidity, but as the movement of air is depended upon to carry the heat and humidity and to distribute it evenly throughout all parts of the kiln, unless the circulation is positive and uniform, the temperature and humidity will vary in different places, which means uneven drying. Further, where the circulation is sluggish or even non-existent, conditions in those particular places are beyond the control of the operator. This means uneven drying and unnecessarily long drying periods.

Another point that might be mentioned is that as air quickly becomes saturated with the moisture picked up from the lumber, warm fresh air must be supplied to remove the moisture as rapidly as it comes to the surface of the stock. That being the case, it is not difficult to see that unless warm dry air is supplied in sufficient volume the rate of drying is retarded and where the air movement is sluggish or non-existent little if any drying takes place. All this points to the importance of circulation and suggests why it should be uniform and adequate in all parts of the lumber piles and in all parts of the kilns.

In most of the kilns operated in connection with woodworking plants the circulation depends on the natural movement of air; that is, advantage is taken of the fact that air rises when heated and drops as it picks up moisture and cools. Thus, in the ordinary kiln we have currents of warm air attempting to rise and currents of cooler, moisture-laden air attempting to drop. These two opposing currents meet in places, often in the centre of the lumber piles, and gradually reach a state of equilibrium, with the result that pockets are formed in which there is practically no air movement.

Air Pockets Delay Drying

In view of the fact that warm air rises and that it tends to follow the line of least resistance it is difficult to see how an adequate even circulation of warm air through the lumber piles can be secured and maintained when depending solely upon the uncontrolled natural movement of the air. If the warm air follows the lines of least resistance in its upward movement most of the air will tend to rise on either side of the piles of lumber, with a slight flow into the edge of the piles. These two currents come together at the top and then attempt to gradually drop down through the lumber, only to be met by the warm air that is attempting to work its way up from the bottom of the pile. The result is that as the ascending and descending currents meet and stabilize in the centre of the pile a dead air pocket is formed, which gradually decreases as the drying progresses, but which also prolongs the drying period for it is usually several days behind the rest of the pile.

From the foregoing it will be seen that some method of controlling and guiding the natural movement of air must be devised before a free movement of air through the piles of lumber can be expected. In the case of a kiln with forced circulation, conditions are somewhat different, as a certain amount of control may be exercised both as to volume of air moving and the rate and direction of flow. Through,

Since it is the air that removes the moisture from the surface of lumber in a dry kiln, the movement of the air must be ample in all parts of the kiln, or uneven drying will result. The drift of smoke produced by some burning substance is often used as an indicator for searching out zones of too rapid or sluggish circulation in kilns.

This method is greatly facilitated by the use of the apparatus shown here which was developed at the U.S. Forest Products Laboratory, Madison, Wisconsin. In this device, the use of which involves no fire hazard, as in burning rope, punk, etc., in the kiln, the fumes of hydrochloric acid are blown across ammonia; and an abundance of harmless, visible fumes are produced. These fumes, being of approximately atmospheric temperature, have little tendency to rise or fall independent of air currents. (Photograph furnished by the U.S. Forest Service.)

a proper arrangement of inlet and outlet ducts it is possible to secure a fairly even flow of air through all the piles of lumber. Even here it has been found that the best results have been obtained when the distance the air must travel in going through the piles is as short as possible.

Control the Natural Circulation

Where natural circulation prevails, the movement of the warm air through the lumber piles is bound to be more or less uncertain unless provision is made for controlling and directing it. This is often accomplished through the judicious use of baffles and

*Assistant engineer, Forest Products Engineering Co., Chicago.

curtains. Often the drying operation may be improved and the drying period shortened by directing and controlling the warm air through simple and inexpensive changes in pile design.

One of the most reliable circulation tests is the smoke test in which what is termed chemical smoke is used. This smoke moves with the air and renders the air currents visible so that they may be followed with the eye. A wide range of variation in temperature in different parts of the kiln is an indication of poor, uneven air movement and if the stock in the centre of the piles is found to contain a high percentage of moisture when the rest of the pile is dry it means that the air has not been moving through the pile. As the lumber should be left in until the centre, as well as the outside of the piles, is dry, such a condition increases the drying cost as it prolongs the drying operation.

If you are not entirely satisfied with the rate of drying or if you find wet stock in the centre of some of the trucks, it would be well to check up on the circulation, for it is likely that that is what is at fault.

The Importance of a Layout Sketch

Should be the First Step When Considering an Improvement or Change in Your Dry Kilns or Yard Storage—Visualizes Your Whole Plant, Helps to Avoid Mistakes and Shows You the Best Arrangement

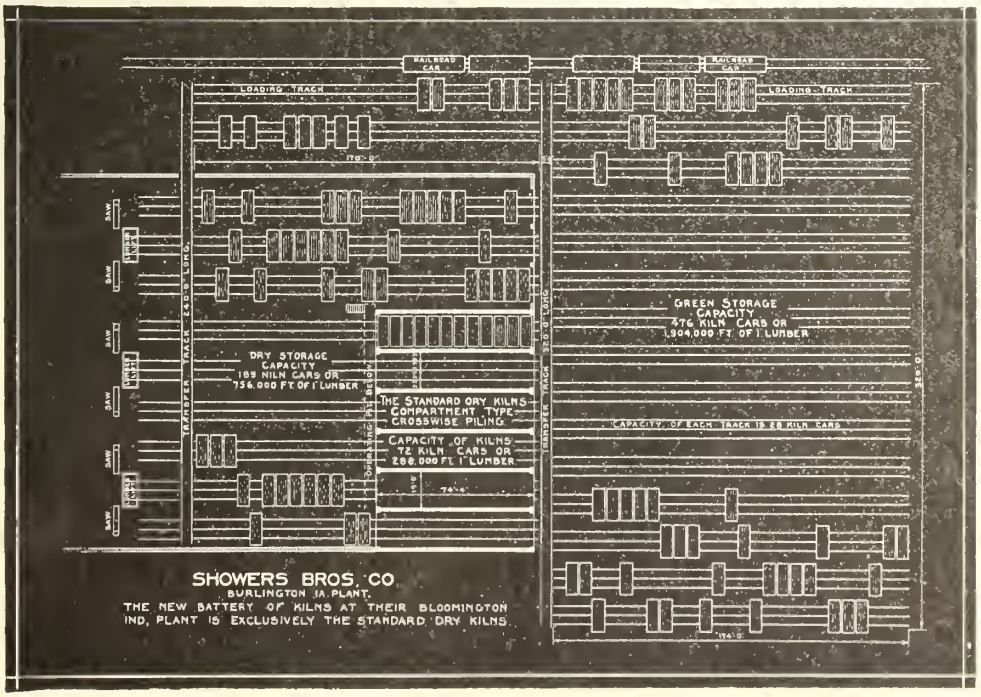
By Victor R. Jose, Jr.*

If you consider and modernizing or changing of your dry kilns or yard storage, your first step is a layout. Most people appreciate this better after they have tried to put in kilns without it. But to get the greatest future value from your kilns and all of the equipment connected with them, it is very important that the entire system of handling the lumber and the type of kiln be crystalled into the form of what is ordinarily called a layout before and binding steps are taken.

The relation of your kilns to the plant, to the cutting room, to the railroad switch, your yard storage and boiler room can be judged more accurately, because they stand out more clearly, by means of a layout. It is often very surprising the way the angles at your property line call your attention to losses of space, unnecessary losses, when you put the space required for your kilns and storage tracks on paper.

The example shown in Fig. 1, (Showers Bros.' Burlington plant) is a sketch made by a layout engineer for the well-known firm of Showers Bros., when they first planned their mammoth new furniture plant at Burlington, Iowa. This layout was made before they had placed their order for kilns and lumber storage equipment because they recognized the possibilities and advantages of visualizing their plans. Of course, the cut shows the sketch reduced from the original size.

An added advantage in a sketch is the fact that such a layout will contain the experiences of the layout engineer which he has gained in many other plants having conditions often similar to yours. He not only presents and advises as to what he has found



RAILROAD CAR
LOADING TRACK
DRY STORAGE CAPACITY 189 KILN CARS OR 756,000 FT. OF LUMBER
THE STANDARD DRY KILNS COMPARTMENT TYPE CROSSWISE PILING
CAPACITY OF KILNS 72 KILN CARS OR 288,000 FT. LUMBER
GREEN STORAGE CAPACITY 476 KILN CARS OR 1,904,000 FT. OF LUMBER
CAPACITY OF EACH TRACK IS 28 KILN CARS
SHOWERS BROS. CO.
BURLINGTON IA. PLANT.
THE NEW BATTERY OF KILNS AT THEIR BLOOMINGTON IND. PLANT IS EXCLUSIVELY THE STANDARD DRY KILNS.

A layout sketch that was made in anticipation of plant extensions

*Of the Standard Dry Kiln Co., Indianapolis, Ind.

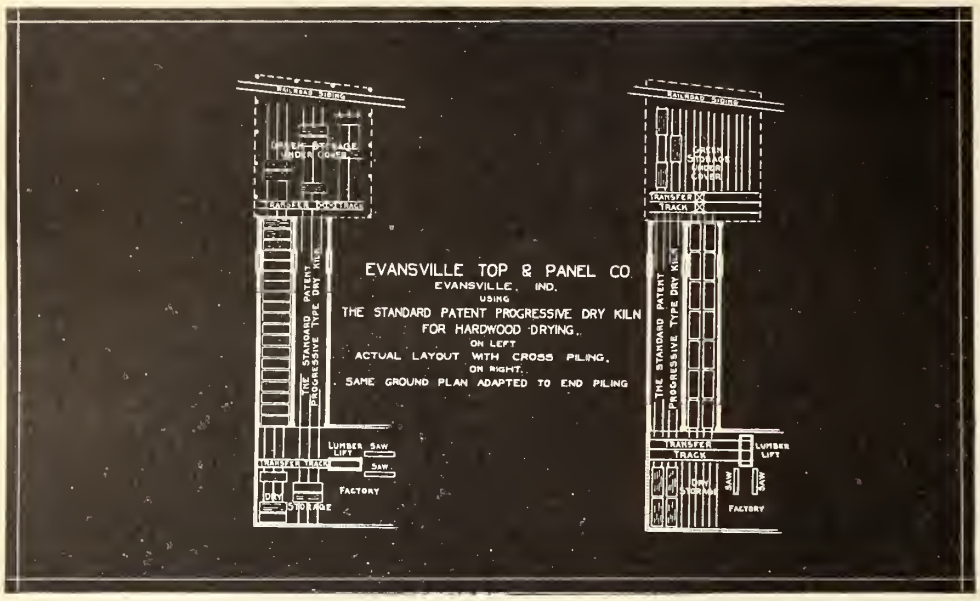


Fig. 2—A layout plan enabled the Evansville Top & Panel Co., to decide the best yard and kiln arrangement for their needs.

of value, but he is able to avoid mistakes which he noticed in other plants and this is often even more important.

In the Showers Bros.' layout the kilns were only one of the important items to be considered in planning their equipment for seasoning their lumber. Enough dry storage space had to be provided to insure against delay in unloading when the lumber was seasoned. Likewise loading capacity is very necessary, and having determined these two points it was necessary to proportion them properly.

After the first layout was made it was immediately seen that, while it had excellent points, the layout as a whole might interfere with future expansion. This might be overlooked without layout, but it was very easy to catch the omission using a layout. The fact that different points are visualized makes it much easier.

The layout also shows very quickly the lines which your production follows, whether it is straight line production or whether any "back tracking" occurs.

Fig. 2, illustrates another great possibility presented by a preliminary layout. The Evansville Top & Panel Company, whose kilns are shown on the left in Fig. 2, were able to decide which type of kiln, cross piling or endwise piling, would best serve their purpose, by making a comparison layout on similar ground plans. You will notice that the truck of lumber at the end of the mill room, the relation of the unloading track to the railroad siding for unloading,

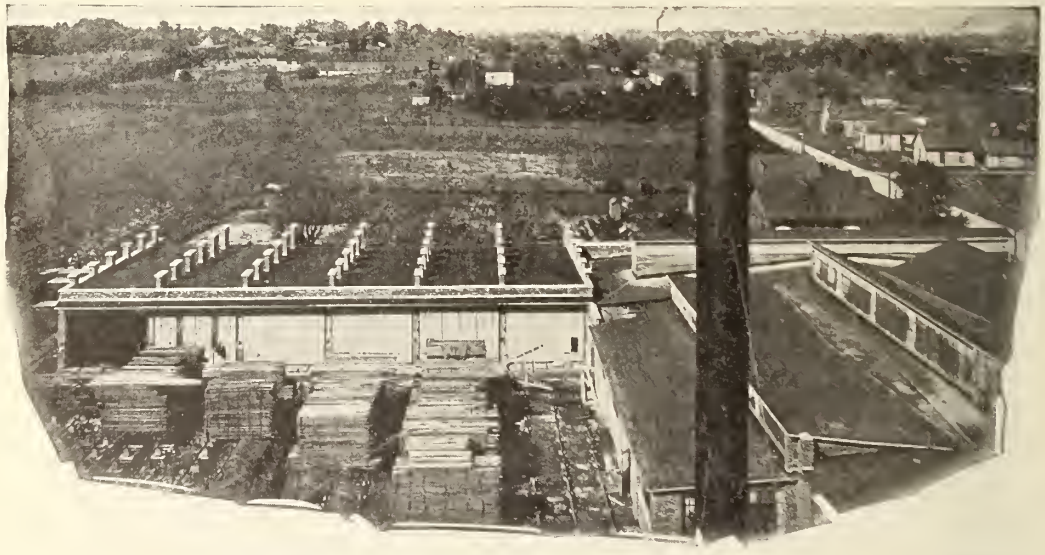

Fig. 3—The Showers Bros. Co's., latest installation of dry kilns worked out in accordance with a layout sketch

location of saws and lumber lift and other equipment were shown in such a way that they could actually determine the best arrangement for their particular needs and avoid errors which often prove very costly in the future.

Many people ask what type of piling, cross piling or end piling, is the better. As in the case of the Evansville Top & Panel Company illustration, many points which are involved in the answer to this question are made much plainer to the person who has had only a little experience, when their advantages

(Continued on page 65)

Basic Time Standards in Woodworking

Ordinary Time Standards Do Not Indicate Operation Times as They Should Do —Comparison of Rates Expressed in Time and Money—Common Terms of Expression Essential Before Comparisons can be Made

By L. R. Wright*

Before discussing basic time standards it might be well to touch on the advantages of ordinary time standards, recently remarked J. F. Hirt, Vice-president of the Forest Products Engineering Co., Chicago, in an address delivered before the Chicago Furniture Manufacturers' Association. Time standards if accurately developed indicate exact machine capacity. By segregating and tabulating the operation times required by each individual part of the various items going through the plant, based on the times indicated by the time standards, the total times for the various machines will give the machine hour requirements of the work in progress.

Taking the machine hour requirements for any given article it becomes possible to promise specific deliveries between department and department and for all orders going through the plant, for the machine hour requirements will indicate just how the work will progress and when it should be ready for delivery.

From this it becomes an easy matter to predetermine labor costs for having the machine hour requirements and knowing the hourly rate paid to the various operators, it is not difficult to calculate the labor costs. If this can be done it is very desirable, but perhaps that is expecting too much. Certainly, the exactness with which labor costs can be predetermined depends entirely on the accuracy of the time standards.

Further, time standards are also used as a basis to pay for the labor involved in proportion to what is produced. By including an incentive in the rates established on the time standards it usually follows that the workmen become more interested and increase their efforts.

In the past, and even to-day in many plants, ordinary time standards were established on past performance or upon time studies, neither of which provide a satisfactory basis for developing standard times. Cost records may indicate what the labor times have been and time studies may indicate approximately what they are, but neither cost records nor straight time studies give any indication as to what the operation times should be. Further, the average workman is familiar with time study methods and when he is being observed he often attempts to mislead the observer. The making of time studies may be likened to a gamble between the time study man and the machine operator and the result is that the standard or rate so established is of very little value.

For instance, suppose a standard is being set on belt-sanding a dresser top. Unless the observer knows the exact amount of pressure the workman is placing on the pad and also knows when the piece has been fully sanded there is no assurance that the rate set bears any relation to what the time should be. In other words, ordinary time standards are only as good as the observer.

Ordinary Standards Not Permanent

Another point is that ordinary standards expressed in rates and tables are not permanent. As a line is changed new standards must be set to cover the new operation times. These new times should not be guessed at, neither is it satisfactory to estimate from previous standards, but further time studies must be made. This means that in the furniture industry where the designs are being constantly changed and

Table 2—How workmen's earnings are kept on the time rate basis

Table 1—Comparison of Performance Standards Expressed in Time and Money

Time studies indicate that certain operations should be performed as follows: No. 1, 11 minutes; No. 2, 33 minutes; No. 3, 41 minutes; No. 4, 18 minutes. These are minimum times. Allowances are added according to the requirements of different operations as follows: No. 1, 4 minutes; No. 2, 12 minutes; No. 3, 9 minutes; No. 4, 12 minutes. This makes established time standards of: No. 1, 15 minutes; No. 2, 45 minutes; No. 3, 50 minutes; No. 4, 30 minutes.

Piece work rates figuring on 60 cents an hour.	Earned time rates regardless of hourly rate.
No. 1. ..... 15 cents	No. 1. ..... 15 minutes
No. 2. ..... 45 cents	No. 2. ..... 45 minutes
No. 3. ..... 50 cents	No. 3. ..... 50 minutes
No. 4. ..... 30 cents	No. 4. ..... 30 minutes

Suppose the hourly rate drops 20 per cent, or on a certain operation you find it necessary to use a workman receiving a higher or lower hourly rate, the rates expressed in money would have to be re-figured to conform to the changed hourly wage rate. For a 20 per cent drop the change would be as follows:

Piece work rates figured on 48 cents per hour.	Earned time rates no change required.
No. 1. ..... 12 cents	No. 1. ..... 15 minutes
No. 2. ..... 36 cents	No. 2. ..... 45 minutes
No. 3. ..... 40 cents	No. 3. ..... 50 minutes
No. 4. ..... 24 cents	No. 4. ..... 30 minutes

Rates expressed in time are flexible. They do not require changes on account of fluctuating wages. They apply to present lines but for all new designs or changes in present designs, entirely new standards should be established. It does not pay to estimate from previous time standards.

*Statistician, Forest Products Engineering Co., Chicago.

where new designs are being brought out twice a year for the January and July markets, the services of one or more time study men would be in constant demand in each plant. It hardly pays to do this as it means a continual expense so that usually ordinary rates soon lapse and the system is discarded.

Since the development of what we call basic time standards all this has changed. From comparative data secured in numerous plants it has been possible to establish basic time standards which give operating time as they should be. This called for the crea-

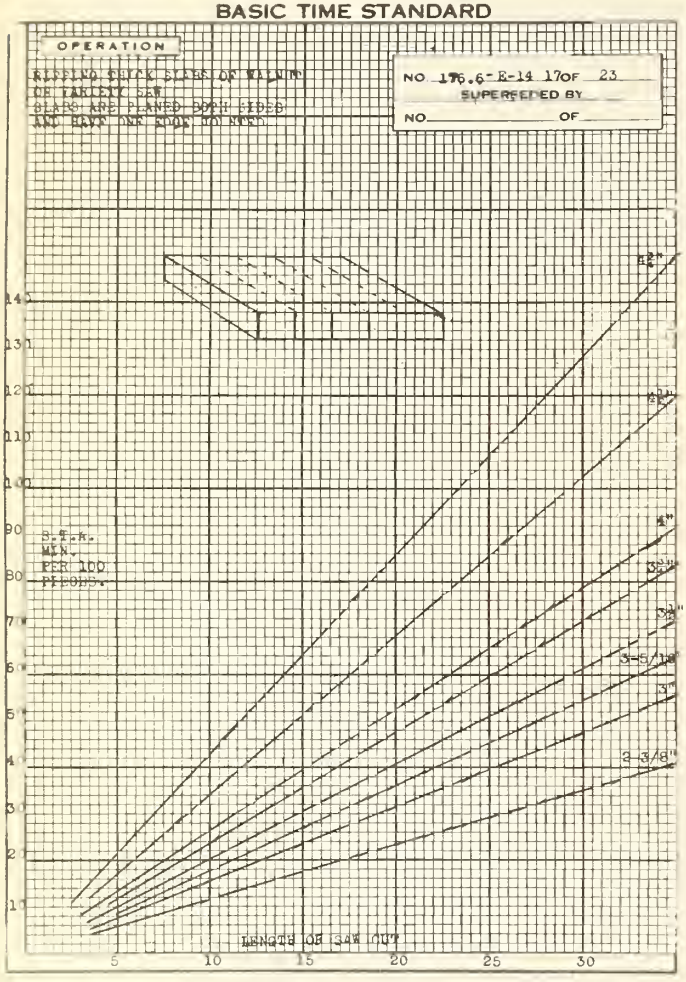

Illustration No. 3—Chart to show the application of basic time standards

tion of a common language or common terms of expressions. The same operation may be performed in different plants in many different ways or on different machines and as a result a comparison of the output or of ordinary standards which may be established does not mean anything. Similarly, two standards established in different plants are not comparable, unless such factor as rates of feed, speed of cutters, angle of cutters, layout of equipment and other details are known. Before results in different plants can be compared all the details pertaining to the operations under comparison must be known and must be expressed in common terms. Comparative data expressed in common terms is the foundation upon which basic time standards have been developed.

Before showing the application of basic time standards I would like to discuss briefly the various methods of paying for labor. Table No. 1 shows a comparison between rates expressed in money and rates expressed in time. Rates expressed in money must be changed to conform to the hourly rate earned by various operators and in corformity with every change in wage levels. Rates expressed in time do not change so frequently because an operation time should not change unless there has been some change in equipment, layout, etc. For this reason time expression rates are in use in practically all industries.

Keeping Track of Earnings

Expressing the rates in time, it becomes an easy matter to keep track of the earnings of the various workmen. The report of earnings form, illustration No. 2, show how this is accomplished. The clock hours are shown in the first column, then the time on day work. This is followed by the time on incentive work and the total earned time, which consists of the total day work time as indicated in that column and the total earnings under the incentive plan. A comparison of the total time earned and the clock hour shows whether the workman exceeded or fell below the standard set. It is usual in introducing a plan of this kind to guarantee the clock hours for a limited period so that a workman falling below is not penalized at the start.

This form also constitutes the foundation of an unusually good foreman's bonus plan. In developing the foremen's bonus, two factors are considered, the extra earnings of his department and a reduction in day work. Usually the foreman is paid 50% of the average "time over" of the men under him and 10% of the amount the day work is decreased below a certain standard. Thus he has two incentives, one to increase the output of his department and the other to cut down the less productive day work. Under this plan it is not necessary to suggest to the foreman that so and so is not producing as he should or that this man should be let out. Every man that is not earning a bonus is losing money for the foreman. It is in his interest to concentrate on the weaker men.

The foreman is given a copy of the report of earnings as issued. He checks over the earnings of those

under him and then tries to bring the "time under" men into the bonus class. If he finds that there are those who seem unable to keep up with the rest he will suggest that they be given work for which they are better adapted or let out altogether. All this has a marked influence on the productiveness of the de-

partment and tends to rouse and maintain foreman interest and incentive.

The difference between basic time standards and ordinary standards are; first, basic time standards are not based on conditions in any one plant or locality but on comparative data from many plants; second, they give operation times as they should be regardless of what the times may be in any plant and third, they are so developed and charted that rates may be accurately and quickly established on new as well as existing designs, by almost any clerk in the organization. This does away with the necessity for further time studies on new lines and means that basic time standards when once installed are permanent.

Application of Basic Time Standards

The wide application of basic time standards may be gathered from the rip saw chart shown in illustration No. 3. The time for ripping walnut squares from glue-up slabs can quickly be determined for lengths from 5 to 35 inches, and thicknesses ranging from 2⅜ to 4¾ inches. To use this chart simply select the length of the saw cut on the lower margin and run up to the curve which applies and then to the left hand margin. The figures there indicate the standard time in minutes required to rip 100 squares.

The example shown in illustration No. 4 shows how basic time standards assist in establishing operation times as they should be—minimum operation times. Straight time studies in a certain plant indicated that band sawing certain pockets for instrument cases required 10.833 minutes while basic time standards indicated that 5 minutes was a fair time for this operation. In order to bring the time down to as near the standard as possible certain changes were made as indicated; first, a narrower blade was used; second, more set was carried; third, a slight change was made in the design and fourth, the operator was coached in the best method of handling the work, with the result that the time was finally reduced to 4.960. Neither straight time study nor ordinary time standards could have indicated that the first time, which was the actual time, was just twice what it should be. In this instance, the fifty per cent reduction in time was due solely to the fact through basic time standard it was shown that the actual time of 10.833 minutes was away too high.

If space permitted other examples of the application of basic time standards might be given and the effect on costs shown. Definite knowledge of what operation times should be is essential before an intelligent effort can be made to reduce labor costs to what they should be.

Can Wood be Made More Durable?

There is Need for Effective Protective Paints to Preserve Wood Against Moisture and Increase its Durability and Dimensional Stability—Ordinary Paints are Not Effective as Moisture Proofing Agents

By Cornelius T. Myers*

About two years ago the writer, in carrying on some research work on wood wheels had occasion to make inquiry among paint manufacturers as to the value of various kinds of paints and primers for the protection of wood against moisture. This inquiry brought out so many differences and variations in opinion as to paint materials and mixture proportions that a more extensive inquiry among paint men was started. This inquiry revealed that:

(1) There was comparatively little technical information to be gained from the paint industry on the relative protective values of different coatings for wood.

(2) The paint industry did not generally recognize the moisture-proofing of wood as a problem, but was concentrating so far as the more reputable manufacturers were concerned on producing paints that would last as long as possible on the surface to which they were applied. In other words, such improvements as have been made have contributed to the life of the coating rather than the life and usefulness of the article which received the coat.

As the demand upon our forests depends to a very considerable extent upon the life of forest products, and as the life of these products in many cases depends to a very considerable extent upon the protection against moisture they receive, the intimate knowledge of protective coatings is a factor of great importance in our lumber conservation program; to say nothing of the possible saving in our large annual paint bill. Wood in its natural green condition has a very limited use as a structural material. Its tiny fibres are cellular in form and contain a large amount of moisture, commonly known as sap, the sap being water containing very small percentages of tannins, sugars, gums and coloring matters. To give wood the physical qualities which make it fit for use in buildings, furniture, truck bodies, wheels, etc., it is necessary to remove most of the moisture.

Moisture in Wood

Wood is said to be oven-dry when continued oven drying causes no further loss of weight. In their green state the woods used structurally have a moisture content of 60 to 120 per cent. of their oven-dry weight, and weigh roughly from 60 to 120 per cent. more than when they are in an oven-dry state. In other words, 35 to 55 per cent. of the weight of a green log is water. In the green log this water exists in two conditions:

(1) Minute particles of water in each tiny wood cell cavity, known as "free water."

(2) The moisture absorbed by the fibrous material which forms the walls of the cells, known as "hygroscopic moisture."

Felled wood exposed to average atmospheric conditions gradually dries, the air taking up its moisture. First the cell cavities slowly give up their moisture. This evaporation goes on until the cell cavities are emptied of the minute particles of "free water" they contain. All that remains is the moisture actually absorbed by the fibres of the cell walls, which are still saturated with the "hygroscopic moisture." Wood in this state is said to be at its "fibre-saturation point." Up to this time the wood does not

*In "Mechanical Engineering."

appreciably change in size or in physical characteristics except as to weight, which of course decreases considerably as it will now contain but 25 to 30 per cent. of moisture instead of 60 to 120 per cent.

Further drying of the wood is necessary in order to increase its strength and hardness, increase its

TABLE 1 APPROXIMATE PERCENTAGE OF INCREASE IN STRENGTH OVER GREEN[1]

durability, enable it to take and hold paint, and in general to improve its condition for the purpose intended. As this drying progresses beyond the fibre-saturation point ,the cell walls give up the moisture they have absorbed, and in so doing they shrink and harden. Under natural conditions this drying process will continue until the amount of moisture in the wood bears a quite definite relation to the average humidity conditions in the particular locality. (See Fig. 1.) In the eastern and north central states, for instance, the moisture content of wood will become stabilized somewhere in the neighborhood of 14 per cent. for what is known as thoroughly air-dried stock. In the arid, southwestern states it will contain a still

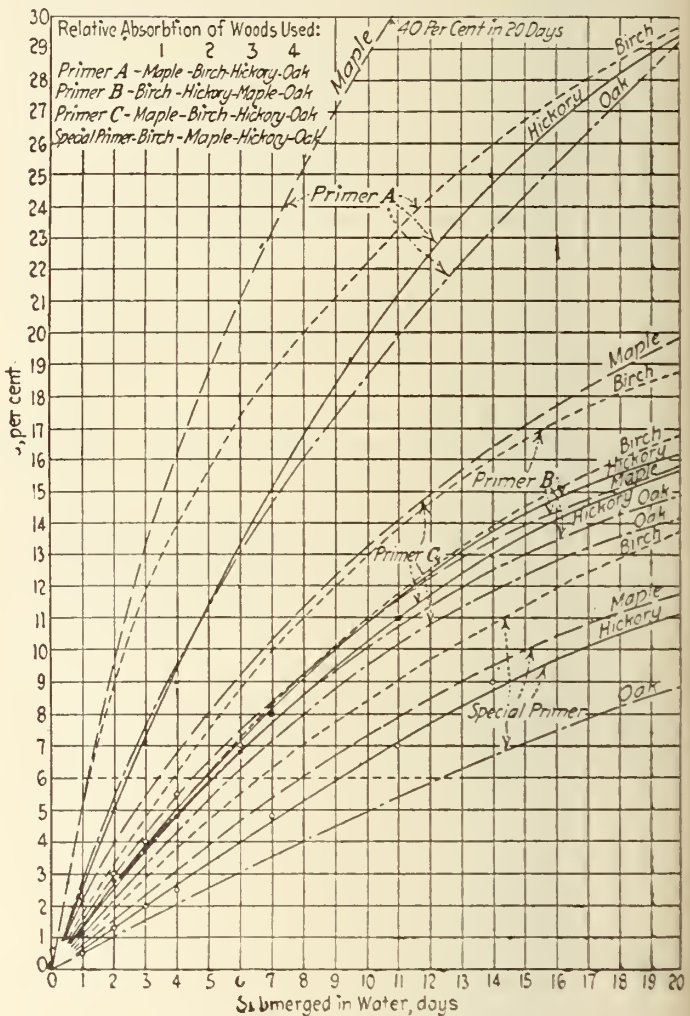
Fig. 1—Relation between the amount of moisture absorbed by wood and the average relative humidity

lower percentage, while in the former war zone of France the wood will normally contain considerably more than 14 per cetn. of moisture. Of course unpainted wood that is exposed to rain and snow will absorb considerably more than 14 per cent., depending upon the dimensions of the piece and the extent of the exposure.

Data secured from the Forest Products Laboratory of the United States Department of Agriculture show that:

(1) Many woods should be dried to about 8 per cent. moisture content to give the best results as to strength, durability, hardness and finish. (See Table 1).

(2) It is also true that if after being dried, and shrinking in the process, wood reabsorbs moisture, it will swell again according to the amount absorbed.



Relative Absorbtion of Woods Used:
1 2 3 4

Fig. 2—Curves showing how the effectiveness of different primers as moisture-proofing agents varied for different woods

(3) The shrinking and swelling along the grain, perpendicular to the grain and tangential to the grain all differ, and very materially, for a given change in moisture content. (See Table 2.)

From the tables referred to it will be seen that it is quite desirable to have wood thoroughly dried, and that steps should be taken to keep it so. But although it is easy to reduce the moisture to 8 per cent in dry kilns, it is difficult to maintain the wood at this point; because of unsuitable protective coatings, or processes, and because of the lack of knowledge as to relative ability of various coatings for really stabilizing the moisture content within a small range.

Protectiveness of Paint

While we know that several coats of good paint may give adequate protection for floors, truck bodies, furniture, wheels or other wooden articles, we by no

means know what paint gives the best protection or what paints will give fairly satisfactory protection for the least money. The test fences, where many different paints were exposed to the same atmospheric conditions, have given some data on the durability of paints, but very little data on the durability of the painted article or its dimensional stability. In durability and dimensional stabilization we are greatly interested; in the first for very obvious reasons, in the second because wooden structures, furniture, etc., are more durable, serviceable, and can be made more simply if their various component parts do not expand and contract with changing weather conditions. The cost of drying could be reduced in many cases, if when dried to a certain point the moisture content could be stabilized. Wood, on account of its very valuable characteristics, could be used in places where metal now seems necessary. A dozen or more prominent concerns in the paint industry are co-operating very commendably in this research work, realizing that the dimensional stabilization of wood by moisture-proofing was a proper function of paint and of world wide importance. There is, however, quite a difference of opinion among these manufacturers as to what materials should be used, and how they should be mixed and applied. During the war the Forest Products Laboratory investigated the moisture-proofing effects of linseed oil and various paints, varnishes and leaf-metal coatings as applied to airplane propellers and other airplane parts made of wood, but this work has not been broadened because of lack of funds.

In order to get some comparative data on the paints and primers now on the market, the following schedule was drawn up by the writer, and tests were made on small pieces, measuring 1 × 1 × 1 in., of hickory, oak, birch and maple by several well known paint concerns:

(1) Dry slowly and completely until pieces cease to lose weight.

(2) Determine "oven-dry" weight.

(3) Allow reabsorption to 8 per cent.

(4) First coating to be applied at 8 per cent. moisture content.

(5) Second coating to be applied at 8 per cent. moisture content.

(6) Third coating to be applied at 8 per cent. moisture content.

Note: 24 hrs. to elapse between 4 and 5, and 5 and 6.

(7) Allow the three coatings to dry for a week under conditions of 70 to 80 deg. fahr. temperature, 40 per cent. relative humidity, under which condition the moisture content of the wood should remain at 8 per cent. even if the wood had no protective coating.

(8) Label and weigh for base weight at 8 per cent. moisture content with protective coating.

(9) Submerge in water at 70 deg. fahr.

(10) Weigh every 24 hr. for first week, every 48 hr. thereafter and determine percentage of increase in moisture.

In general, the results of the tests showed that paints of the ordinary brands and formulas were not very effective as moisture-proofing agents, even when three coats were applied. One paint concern after testing its standard brands, did a little experimenting, and without much difficulty was able to produce a special primer that was several times as effective. The curves in Fig. 2 show quite emphatically the variation in effectiveness of the paints used. Averaging the results for hickory, oak, maple and birch, it took about six times as long for these test pieces to absorb an extra 6 per cent. of moisture when coated with the "special" as when coated with the standard "A." There is every reason to believe that much better results can be secured and with less than three coats. Preliminary tests with a casein solution indicate that it has water-proofing qualities, which, for some classes of protection, may be very valuable. The same is true of some of the pyroxalin compounds. Varnishes are in general more effective than paints, but in the protection of wheels its application was not suitable for primary coats.

Need for Research

What has been said so far shows the need for research work on this subject. Cabinet and furniture makers are vitally interested in a coating which will prevent wood from "working," shrinking and swelling, due to atmospheric changes in winter and summer. Interior woodwork could be greatly simplified if the dimensions of each particular piece of wood remained the same or varied but a very small amount. Flooring, decking, paneling, etc., would be greatly benefited if it did not "work." Many wooden structures would be simpler and more permanent if so protected, and with thoroughly dried timber they would either have a greater factor of safety or could be built with less lumber. Many other advantages will develop as thought is given to the subject—the dimensional stabilization of wood by rendering it moisture-proof to some substantial degree.

It is well known that shingles and weather boards fastened with old fashioned wrought-iron nails stay tight longer than those in which the modern steel nail is used. The reason for this is that the steel nail rusts and is flaked off by the movement, or "working," of the piece through which it is driven. A nail tightly driven is practically sealed against external moisture by its head and the paint around it; but if moisture reaches the nail by the capillary action of the wood fibers, it will rust in spite of end sealing. Then too, the moisture and capillarity of the wood cause the "working" that rubs off the layer of rust and exposes the nail to continuous corrosion. The working also abrades the wood and leaves the familiar large, rust-stained hole around an attenuated nail. The same conditions apply to the bolts and other steel fastenings in farm machinery, wagons, motor-truck bodies, and a long list of other articles. It is of vast importance in wood construction, therefore, that we have paints to protect the wood from absorbing moisture. Ordinary paint does not effectively do this except when a large number of coats is applied, and so far as the writer has been able to find out, there has been little or no attempt to produce a paint that will do it.

The Importance of a Layout Sketch

(Continued from page 60)

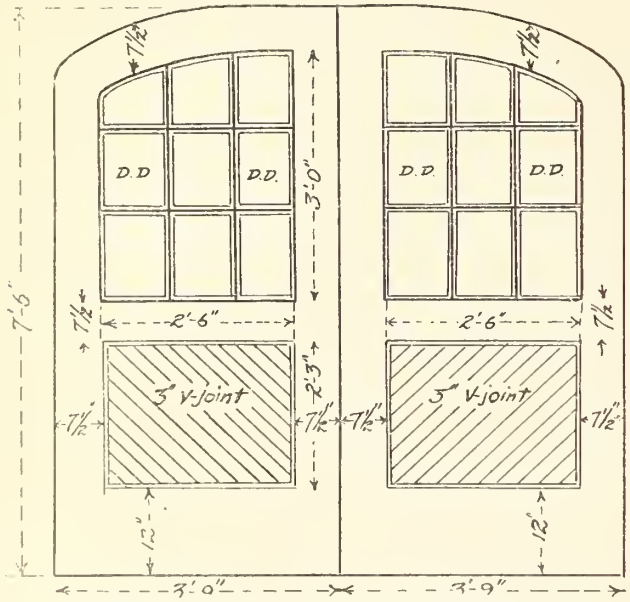
and disadvantages are shown in a sketch. It is possible to obtain a sketch or layouts like these of other plants and make a comparison on actual conditions as well as theoretical. And anyone who is checking up his dry kilns, even though not planning immediate action, will do well to get these for the sake of new ideas and helps which they often present.

Fig. 3, shows latest installation at Bloomington, Ind., plant of Showers Bros.' Furniture Co.

What is the Right Cost for Garage Doors?

Can a Difference of 144 Per Cent in the Estimated Cost be Justified?—Although the Job is Comparatively Simple, no Two Estimates Agree as to the Amount of Material Required

For this issue of the "Canadian Woodworker" a rather simpler job was selected for our cost study purposes, the idea being to pick out a piece of work that is more in line with what the average mill is accustomed to handle. On several occasions our contributors to this department, in sending in their figures, asked that we choose a job that was more ordinary and which was more like the work that was constantly running through their plants. We felt that the pair of garage doors illustrated met these requirements and consequently, we asked for estimates of the net cost of producing these, with results as shown in the accompanying table. It is very interesting to look over these figures and compare them, for there seems to be just as big a difference, or possibly more, as in the case of the more intricate jobs which we have used in some of these cost studies. It was rather



Ten millmen figured on this pair of garage doors. As shown in the accompanying table the cost was estimated to be anywhere from $23.69 to $57.84

expected that with a more standard line, estimated costs would show a smaller range of difference and that within close limits they would be nearly on a par. However, the fact that there is 144% variation between the low and high figures, with the others well distributed between, indicates that even on standard lines millmen are not yet well versed in figuring costs. Of course, it must be understood that some allowances must be made for the difference in conditions at different plants, for the different prices they have to pay for their lumber and their labor, etc., but notwithstanding all this there should not be the large discrepancies that have characterized practically all of these cost studies. Our contributors to this department apparently agree with this for we are constantly being assured by them that they realize how bad the situation is and are anxious to co-operate with us in trying to bring the facts before the millmen so that they may see the error of their ways and attempt to correct them. Just to show with what interest some millmen look upon this series of articles, we quote from the letter of one Ontario firm. "We take it," they say, "that the ten or twelve firms who are contributing are representative firms in Ontario. Would it not be a good move some time this winter to attempt to bring these firms together and endeavor to solve some of these problems together. The variations in estimates are out of all reason and it looks as if we were open for information along this line." While the firms that participate in these studies are not all Ontario firms, but are operating in some of the other provinces, it might be possible to bring together a sufficient number of firms in the same district to make a study of these problems. What do you think of the suggestion? If you are favorable, it might possibly be worked out.

144 Per Cent Difference

Taking up the garage door job specifically, it will be seen that the total cost, without profit, varies from

No.	Lumber	Waste	Bench Hrs.	Rate	Machine Hrs.	Rate	Commercial Burden	Total
1	$ 8.64	10%	4	.60	6	.90	30%	$23.69
2	7.41	25%	5	.80	5	1.25	20%	25.55
2a	13.21	15%	7	.87	3	1.13	20%	29.03
3	8.77	10%	8	.85	5½	1.50	20%	32.18
4	13.20	20%	9	.85	4	1.25	20%	34.61
5	10.50	25%	12	1.00	4	1.25	15%	34.85
6	12.82	20%	7	.90	8	1.20	20%	38.14
7	16.80	20%	11	.85	5	1.07	20%	43.40
8	16.61	20%	6	.80	8	1.50	20%	43.81
9	20.95	20%	13	1.00	9½	1.50	20%	57.84

$23.69 to $57.84, a difference of 144 per cent. The remaining figures are pretty well scattered between these two limits although the majority are between $32 and $38. In the particular items that go to make up the estimates, the amount of labor required shows quite a great variation. Bench hours, for example, vary from 4 to 13 and machine hours from 3 to 9½. On the matter of lumber there is quite an unnecessary difference in the number of feet that are estimated to be required on this job. The lowest estimator figures 84 feet net, while the highest figures 110 feet net. Surely the job is simple enough to enable estimators to take off their quantities with a reasonable degree of accuracy. Remember these are net figures without waste. For waste some figure as much as 25% and some as low as 10% although 20% seems to be the most prevalent figure.

We have repeatedly pointed out that commercial burden is a very important element in figuring costs and we have time and again urged our readers to take full cognizance of this factor and give it the rating that its importance deserves. In this instance 20% is the commercial burden rate in 7 cases out of 9, the other 2 being 15% and 30%, the 15% figure being much too low in our opinion. This factor of

commercial burden has to cover such a large number of items that it cannot be kept low and cover them adequately. We are never surprised to see high commercial burdens because we know that many plants operate in such a way that this factor is an unusually high one. Of course, in such a case it is up to the plant operator to make every attempt to keep his overhead down so that the burden factor will be as low as possible.

Need for Improvement

Judging the matter as a whole, we can draw from this particular study the same conclusions that have been formulated in our previous cost articles, viz., that millmen need to improve their practices with regard to figuring costs and need to make a more important study of the elements that enter into their costs so that they can estimate intelligently and with reasonable assurance of deriving a figure that will be as closely as possible equivalent to the actual cost of turning out the job. The Millwork Cost Bureau to which several Canadian firms belong, is doing a most excellent work along this line but whether you are members of the Millwork Cost Bureau or not, you can do considerable yourselves toward remedying the situation as far as you are concerned and thus pave the way for profits that are surer because they are based on an exact knowledge of what it costs to produce your goods.

We have deliberately left out a suggested cost study for next month as we would like to hear from our readers if they care to have these articles continued. They have been running now for practically a year and we hope that the lessons which they have been intended to teach have properly impressed themselves upon those who have taken part. At the same time if our readers would like us to continue these articles, we will gladly do so. But please let us have your opinion on the matter.

Differential Price List for Box Makers

A Method For Figuring the Sales Price of Box Shook that Will Allow of the Same Profit Irrespective of the Size of the Order—Will Assist Both Manufacturers and Buyers

The "differential price list" is a method for figuring the sales price of box shook which has recently been issued by the National Association of Box Manufacturers, Chicago. Briefly, the system will enable a man to sell any type or size of box, knowing that the same relative profit will be received whether the order consists of one, one hundred or more boxes. In a recent issue of the bulletin of the Association appears the following comment regarding the purpose and application of this differential price list.

All box manufacturers agree that while they may be making a profit on a certain line of orders, there are boxes or shook produced which, owing to complications in manufacture, size or quantity ordered, do not bring in the same profit, and in fact many times, when costs are figured, will actually show a loss. The use of the differential will eliminate the manufacturing of boxes at less than production cost. It gives the relative sales price for all orders regardless of size and whether one box or one thousand; it considers the amount of material in each shook and box, what should be the additional sales price for a small box as well as one of unusual size when compared with the box with the average feetage, or one of easy construction. It calls to the attention of the manufacturer the various small items that go to make up the cost of producing boxes, such as corrugated fasteners, printing, the changing of guides on account of small orders and tying of shook for delivery.

Once the list is installed in a manufacturer's sales department and customer's boxes are figured according to its rules, it eliminates the necessity of refiguring the cases when prices change on account of change in manufacturing costs or the cost of raw material.

The list price that will be placed on the card index carried by the manufacturer never changes. The discount to apply to that list price will change as conditions warrant. Once the list has been installed, it will simplify quotations, for all that is necessary is that the manufacturer determine the discount, and any clerk in the office knowing the discount can quote the price on any order with the assurance that the same relative profit is secured that has been considered necessary by the head of the department.

Its Use With the Customer

It is not necessary that the buyers of box shook be handed a copy of the differential list, although this can be done to the advantage of the manufacturer as well as the buyer. The cost of the differential has not yet been determined, but will likely be in the neighborhood of $5 per copy. Shook manufacturers using the differential list as a basis for making all quotations will find it to their advantage to give customers the list price on all shook they are likely to order. Such a letter will show the customer's box number and opposite the list price, which, as stated, never changes. After the customer has been advised of the list price, it would in the future be necessary only to give the customer the discount to apply to that list, which would allow him to figure the price of his shook. It would be an easy matter for the box manufacturer, once he has placed the list price on the various customers' boxes, to put out a weekly or monthly quotation sheet to his customers, such quotation sheet to merely give the discount in effect at time quotation is made.

Box manufacturers who have used the differential in the way outlined have found that the discount system of quotation is welcomed by the shook buyer.

Shows the Minimum Price

Possibly one of the most valuable features of the differential list is that it definitely shows the box manufacturer the minimum price that can be quoted and cover replacement costs, labor, overhead and all other items that go into the cost of shook production. This is of value in meeting competition. A plant that is efficiently organized and that can manufacture at a minimum cost will know that if business be lost to them, it has been taken by one not knowing costs.

therefore at a figure that means an actual loss to the successful (?) bidder.

There is a wider range in the profit received on the individual sizes furnished by box manufacturers and where buyer requests quotations on a relatively large list, the manufacturer of shook figuring on that list will find that the actual profit per size will vary to a large extent. The differential list changes that condition so that the relative profit on each size in an order will bear its proper percentage of profit.

In figuring in competition with manufacturers not using the differential list, there is no question but what if the competition be severe the bidder using the list would receive a certain part of the order, the balance going to other factories, and upon analysis the manufacturer using the list would find that he had taken the profitable part of the business.

There are many ways in which the differential price list can be used to the advantage of both buyer and seller.

In issuing the differential price list the association realized that additions would be made from time to time to cover conditions that would arise in the industry. For that reason the list has been issued in loose-leaf form, so that any page can be corrected without destroying the book, and additions can be made as found necessary.

The association will keep a permanent record of its distribution, so that when changes or additions are made it will be possible for each owner of a list to receive the changes and to know at all times that his book is up to date.

Should the Lumber Manufacturer Make Box Shooks?

The competition that box makers have to contend with when lumber manufacturers attempt to market shooks was characterized as very harmful by L. F. Powell, president of the Box and Shook Makers Association, in the course of an address to the North Carolina Pine Box and Shook Manufacturers Association. Mr. Powell's remarks in this connection were:—

"I grant you that the lumber manufacturer or anyone else has a perfect right to make boxes, but before doing so they should acquaint themselves, first, with the methods of making boxes; second, with the methods of figuring accurately the contents of a box and, third, the method of arriving at the actual cost of producing a box. If they will watch these points we would not have the indiscriminate and ridiculously low prices that are being made to-day by some of our lumber manufacturers who are attempting to sell box shook.

"When a lumber manufacturer goes into the shook market and offers a shook at a lower price than it can be made and sold at a profit, he is not merely hurting the box manufacturer, but is also cutting at the throat of his fellow lumber manufacturer, because it soon becomes generally known throughout the territory in which he sells that a new price has been established on a certain standard box, and every buyer at once begins to hammer the shook manufacturer down to that point or below, with the result that the shook manufacturer is forced to do one of three things: Reduce his price to meet this unfair competition, or continue to make the box at a loss, or else give the customer an inferior package, either one of which cannot stand. I have never felt that it is fair to the trade, nor to our industries, for experienced lumber manufacturers to attempt to market their low grade lumber by manufacturing it into shook. I am certain that no lumber manufacturer has ever made, but on the other hand has lost, money through such venture.

"In mentioning this phase of the lumber business, I wish to make it clear that I have no personal grievance against any lumber manufacturer who is making shook. I am looking at it from the broad standpoint of the industry as a whole, and I believe it will be agreed that it is harmful to both the lumber and box manufacturers."

W. M. Pryor Heads W.M. Ritter Lumber Co.

At a meeting of the directors of the W. M. Ritter Lumber Company, held in Columbus, Ohio, recently, W. M. Pryor was elected president of the company succeeding W. M. Ritter, the founder of the Company, who has been its president since its organization more than twenty years ago. At the same meeting, Mr. Ritter was elected to the newly created office of chairman of the board.

This change in the corporate organization of the company does not mean that Mr. Ritter will be less

Mr. W. M. Pryor

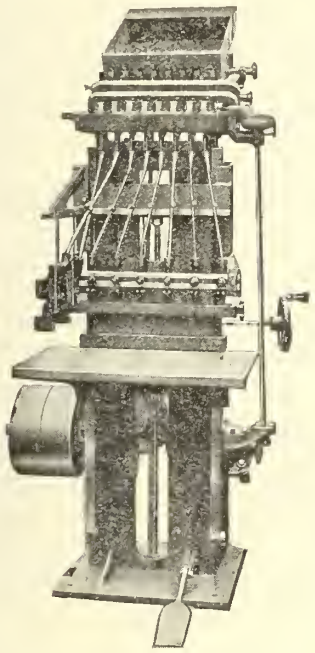
active in directing the policies of the company. The change has been made at his request to the end that he may be partially relieved of executive duties, which, by reason of the rapid growth and expansion of the company, and the multiplicity of his other interests, have become burdensome to him.

The new president of the company is 44 years of age and has been in the service of Ritter interests for more than twenty-five years, during which time he has served in almost every capacity connected with the business, and for the past five years has occupied the position of assistant to the president. He will be remembered by many as traveller in Canada some years ago for the Ritter organization.

Machinery & Equipment

Scotch Box Nailing Machines

It is now possible to procure in this country the well-known box nailing machines made by Matthew Wylie & Co., Limited, of Glasgow, Scotland, who are now prepared to meet any demands that the Canadian trade may develop in this connection. The products of this firm, which include box nailing and cleating machines of all descriptions, have established an enviable reputation in the Old Country and should appeal to Canadian buyers in the box machinery market. The Matthew Wylie line includes machines of all sizes and capacities for plain or zigzag nailing. They are said to be especially easy of operation, entirely automatic and instantly adjustable. A typical nailing machine is shown in the illustration. Those interested will receive a catalogue on request.

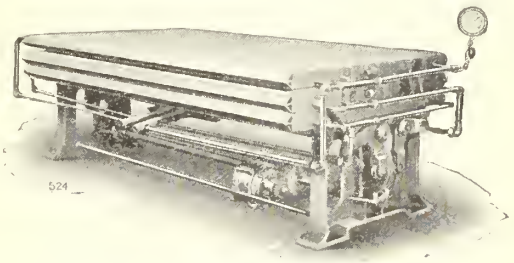


One of the Matthew Wylie line of box nailing machines

Merit Veneer Re-Drier Made in Canada

Canadian woodworkers will be interested to know that Cowan & Co., of Galt, Limited, Galt, Ont., are now making and selling in Canada, under license from the Merritt Engineering & Sales Co., Lockport, N. Y., the well-known "Merit" three plate veneer re-drier. This machine, illustrated herewith, is a horizontal hot plate press in which the heat of the plates converts the sap and water of the wood into steam and the press action holds the sheets flat while they dry out. The pressure upon the veneer is the weight of the plate above it and this is lifted periodically by a power "breathing movement" which forcibly expels moist air and gives opportunity for the veneer to shrink.

The machines are used for drying green veneer for centre stock and for re-drying and flattening veneer for the glue press. The heat is applied uniformly to both sides of the veneer and the edges and ends of a sheet dry no faster than the centre. No checks or splits are produced. The surface cannot become dry or case hardened while there is a particle of moisture inside the wood to be converted into steam and come to the surface.

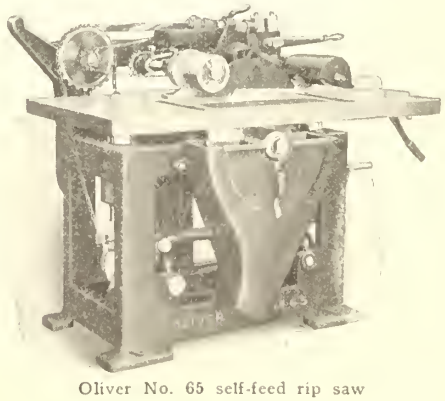


The Merit veneer re-drier made by Cowan & Co.

The machine is electrically driven and is piped for connection with the factory steam line. It is designed for plants having need of a re-drier of moderate cost and of limited capacity. Three sizes are built; No. 1, 2 and 3, having plate sizes 100 in. x 52 in., 84 in. x 54 in. and 72 in. x 36 in. respectively.

Oliver Self Feed Rip Saw

The accompanying illustration shows the No. 65 self-feed rip saw brought out by the Oliver Machinery Co., Grand Rapids, Mich., and which is claimed to be an improvement over other self-feed or power feed rip saws, in its safety features and in the dust chute for easy connection to the exhaust system. The machine is designed for ripping all kinds of lumber and is adaptable to the ripping of rough stock as well as finished stock and is recommended to the operators of mills and shops handling stock in quantity. The saw arbor is mounted on a frame, the frame having vertically adjustable table with an in-feed spur roller made corrugated or smooth according to the requirements of the work going into the machine. This roller carries the stock through the saw and across the top of table.



Oliver No. 65 self-feed rip saw

The machine will take saws up to 18 inches in

diameter and will cut up to 5 inches thick or rip up to 24inches wide. A gang of six saws with 1 inch space collars may be used at one time. Indeed, the machine might be called a gang rip saw. There are three rates of feed, 80, 110 and 140 feet per minute. Some of the special features claimed for this machine are as follows: Quick acting adjustment to feed rollers; quick action to adjustment of and locking of ripping fence; quick raising and lowering adjustment of table; has three powerful and rapid feeds, 80 feet, 110 feet and 140 feet per minute; will take stock having 3/4 inch difference in thickness without readjusting feed rolls; has outside bearing on drive side of machine; has mechanism for absorbing shock on the feed rolls, which overcome any jerks on starting the stock through the machine.

Careful attention has been paid to the safety feature of this machine. The lower portion of the saw is thoroughly guarded by means of the dust chute and the cover; the upper portion runs in a guard carried by the feed mechanism.

The table is 33-1/2 inches by 56 inches, vertically adjusted by a lever locking cam. The saw arbor has self lubricating chambers. The machine may be arranged for motor drive by placing the motor in place of the countershaft.

Information and Inquiries

You are cordially invited to make use of this department

Doll Carriage Gearings

68 St. Andrews St.,
Galt, Ont., Sept. 18 1922

Editor, "Canadian Woodworker,"

Can you inform me of the names of firms that manufacture the gearings for doll buggies?

Thanking you for your trouble, I remain

Yours very truly,
A. C. Johnston.

The E. R. Wagner Co., North Milwaukee, Wis., and the H. N. Thayer Co., Erie, Pa., are firms that specialize in the manufacture of gearings. The Gendron Manufacturing Co. Ltd., 137 Duchess St., Toronto, Ont., may be able to supply your needs although they make the equipment primarily for their own use.

Wants Three-Eighth-Inch Wooden Balls

74 Niagara Street
Hamilton, Ont., Oct. 17, 1922

Editor, "Canadian Woodworker."

Can you furnish me with the name and address of a firm that can supply me with 3/8 inch wooden balls. I fail to find the same advertised in your "Canadian Woodworker & Furniture Manufacturer," but have heard that there is a firm somewhere in Toronto.

If you can oblidge me, your service will be greatly appreciated.

Yours truly,
Edward Earl.

The following Toronto firms can supply balls of the type specified, provided that a sufficient quantity is wanted to justify their turning out the work: Ontario Handle Co., 411 Manning Chambers; Ewing and Murphy, 18 Cameron St.; Kerr and Brown, 1536 Dundas St., West; H. E. Hunt, 337 Leslie St. Among the firms outside of Toronto that can meet your requirements are the Canada Wood Specialty Co., Orillia, Ont.; J. H. Connor and Son, Ottawa, Ont., and Wood Turning Products Ltd., Fenelon Falls, Ont.

Manufacturers of Veneers in Canada

Orange, Mass., U. S. A.
October 17. 1922

Editor, "Canadian Woodworker,"

Can you advise us where we could obtain a list of the manufacturers of veneer in Canada? Please accept our thanks in advance for any information you can supply.

Yours very truly
Rodney Hunt Machine Co.

There are only three manufacturers of veneers in Canada as far as we are aware. They are the Waterville Veneer and Panel Co., Waterville P. Q.; Guelph Patent Cask Co., Scotstown, P. Q., and Sam Lacaille, Nominingue, P. Q.

Dealers in Rattan and Cane Products

Windsor, Ont.,
Oct. 17, 1922.

Editor, "Canadian Woodworker."

Please tell us where we can procure rattan and cane products in Canada or any books pertaining to rattan or reed work for furniture.

Yours truly,
R. S. Buckwell.

The E. T. Carter and Co. Ltd., 84 Front St., East, Toronto, carry a full line of rattan and cane products and will probably be able to fill your requirements. We do not know of any text books dealing with rattan or reed work. Possibly some of our readers can help us out.

Cost System for Woodworking Plants

Montreal, P. Q.,
October 13th. 1922.

Editor, "Canadian Woodworker,"

A client of ours has asked for information in connection with a system of costs accounting for sash, door and wood-working factories. We are writing to know if you have anything on the subject or can advise us where such can be obtained.

Yours very truly,
Stinson-Reeb Builders' Supply Co.

It is possible that you may get the information you desire regarding a cost system from Carle M. Bigelow's treatise entitled "Installing Management in Woodworking Plants," in which book about sixty pages are devoted to cost accounting. This book may be obtained from the publishers, the Engineering Magazine Co., of New York or through the "Canadian Woodworker." Your client may also be benefited by reading the articles that have frequently appeared in the "Canadian Woodworker" on this subject. A perusal of back files will disclose much information relating to cost systems. We also suggest your getting in touch with the Millwork Cost Bureau, 605 North Michigan Ave., Chicago, which is an organization aiming to improve the status of costing in the millwork industry. They will be glad, we are sure, to explain their objects and the system which they recommend.

Upholstering and Trimming

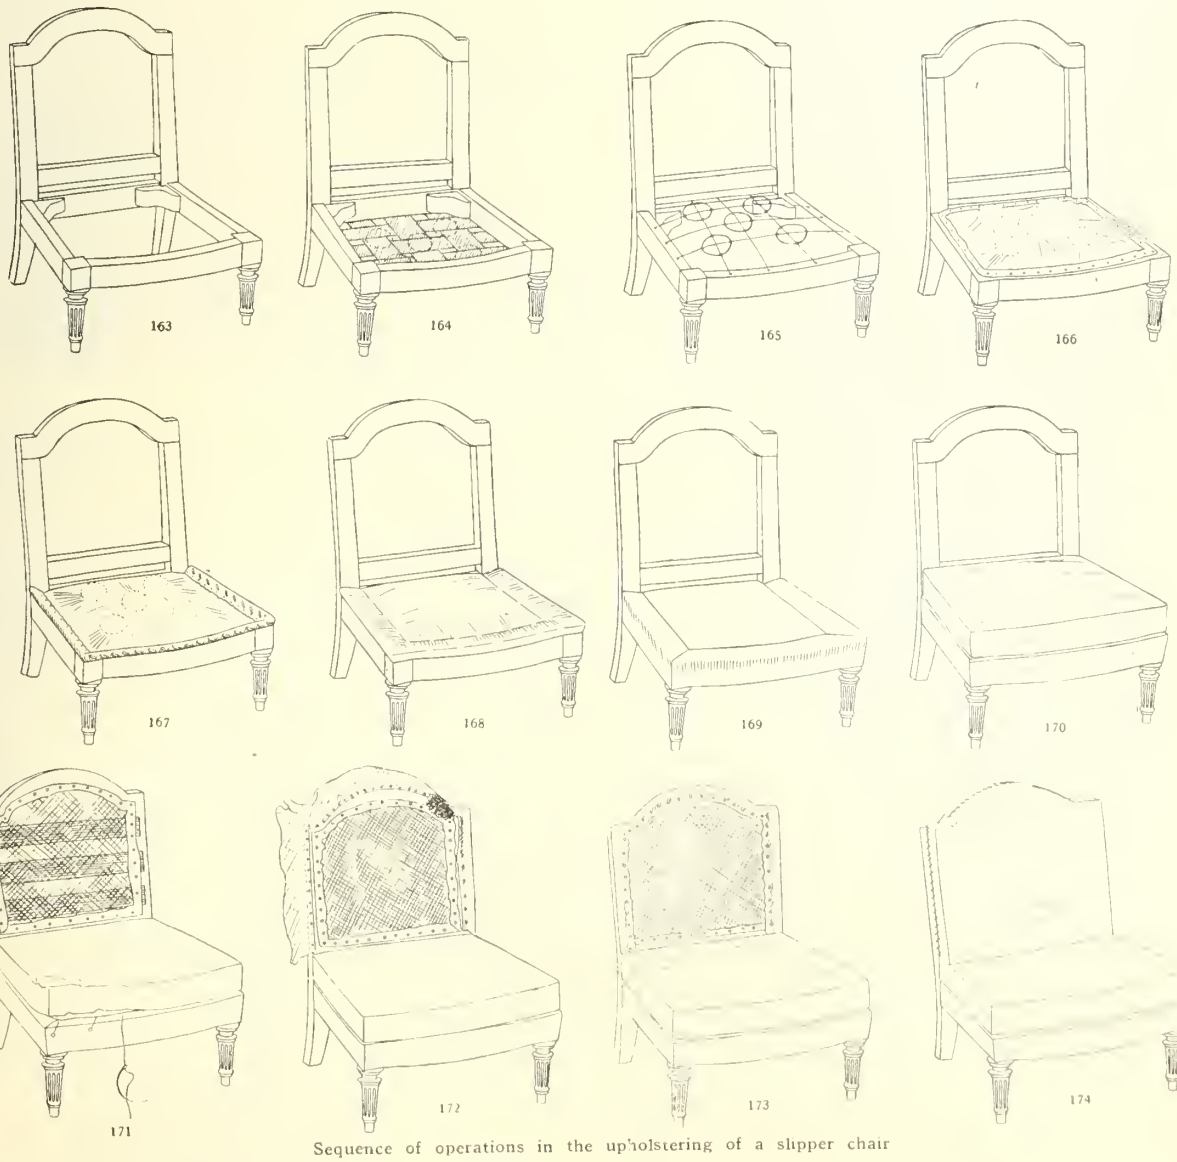
Method of Upholstering a Slipper Chair

Low Seated Piece Requires a Treatment Especially Suited to its Particular Use and Proportions

While there is a great similarity in the treatment of all chairs with down cushions irrespective of their shape, there are certain individual pieces which require a treatment distinctly adapted to their own use and proportions. Of this description is the slipper chair, the frame of which is illustrated in Fig. 163, and the upholstery of which is described in "The Upholsterer."

This chair is particularly used for boudoir purposes and is kept always very low, the seat being not over fourteen inches from the floor. This chair is treated as an ordinary spring seat, being webbed in the usual way for five springs as shown in Figs. 164, 165 and 166.

Canvas or canton flannel for the nosing is next tacked around the front and two sides of the chair and back-tacked on the top of the rail close to the front edge, stuffed up and tacked on the top of the rail as shown in Fig. 167. The edge thus formed may be stitched as indicated, after which a light coating of hair is placed over the springs and the whole covered in muslin as shown in Fig. 168. In this figure it will be noticed that we have indicated the stitching down of the muslin to the canvas so as to provide a

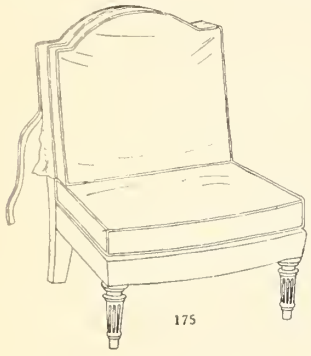


Sequence of operations in the upholstering of a slipper chair

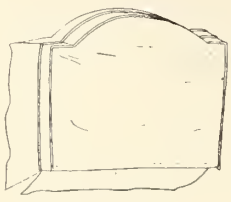
dip about 4 inches from the edge of the chair, which will compensate for the rounding of the bottom of the cushion.

A piece of covering, sufficient to make a complete border is back sewed at the point of this stitching as shown in Fig. 169 and the entire border covered in the usual way.

The centre of the seat may be left in the muslin because for this chair, as will be shown in the next



175



176

stage, the cushion is not intended to be removable. After the cushion has been made and covered after the method previously described in connection with down cushions, it is fitted into place on the seat and the bottom of the cushion is blind stitched to the fabric which covers the nosing. The stitching should be 2 or 3 inches in from the edge of the cushion in order that the cushion may appear to lie on the chair of its own weight and not reveal the fact that it is confined by sewing. The border of the seat cushion is not over 2¼ to 2½ inches high, therefore stitching 2½ inches in from the edge will be quite sufficient.

Also in Fig. 171 the back of the chair is shown canvassed with three strips of webbing across, which provides the foundation for the back cushion, the webbing and canvas both being attached to the front or face of the frame. A piece of canvas or canton flannel is now back-tacked around the three outside edges and tacked in the same way as was suggested for the seat, and a nosing not over 1 inch high is stuffed up as indicated in Figs. 172 and 173.

This nosing may be stitched or not, according to the way in which the nosing has been filled up. The back cushion is now made about 2 inches thick, pattern being taken so as to make a good fit, of the shape of the back. After filling it is sewn all around to the edge of the nosing as indicated in Fig. 174.

The cover is next constructed in the manner already explained in connection with other chairs, the border being piped. In addition to the width of the border, a strip about 3 inches is also provided to act as a second border and cover the edge of the frame.

A welt is provided where this extra fabric joins the cushion as well as a welt on the face of the cushion. The cushion cover is built into place over the cushion, and if desired may be very lightly attached to the nosing in the same manner as the cushion is attached, turning back the surplus cover of course and sewing from underneath.

The final operation consists of padding the edge of the frame and nosing with a layer of wadding and the fabric which has been attached to the cushion for the purpose, serves as a back border and is now tacked into place and the cover welt is also tacked on the outside back at the edge of the frame, so as to give the appearance indicated in Fig. 176 of the double back cushion.

How Upholstery Leathers Are Manufactured

The Various Processes in the Production of Fine Grade Leathers for Furniture Use—What Constitutes Good Leather

By Julian B. Hatton*

The art of making leather may be traced back to the remotest periods of the early civilizations. The Chinese, the Egyptians, the Babylonians, the Persians, the Greeks and the Romans all possessed some skill in tanning. Probably the first method was sun or smoke drying, and treatment by fats and oils such as our own American Indians used. The Egyptians were very deft at finishing leather and were skilled in dyeing, embossing, painting and gilding leather. Some of their product still exists, although manufactured as long ago as 1000 B. C. This demonstrates why genuine leather always pays for its installation and why tanners claim "there is nothing like leather."

In choosing hides for upholstery leather, the Western packer steers are generally selected as they are large and spready and free from butcher cuts. During the war these hides rose in price from 12 cents to 52 cents per pound. They have now dropped and the price of leather has also declined, until it is undoubtedly the cheapest basic commodity.

To change from a thick heavy steer hide covered with hair and salt and liable to putrefaction if not taken care of, to a clean, soft and durable piece of leather with a handsome finish is a process requiring many operations and much careful handling. The big packers are a great source of supply to the tanners and from them the leather companies buy many thousands of hides yearly.

The hides are delivered to the hide house in carload lots of 800 or more, each being separately bundled. In the hide house they are unrolled and trimmed of all the long shanks, the tail and head. They are next taken to the beam house and thrown into paddles of clean cold water and cleansed of all dirt, manure and salt. They are then fleshed by being thrown into a fleshing machine, a machine with a spiral knife roll, which closes down on the hide and scrapes off all loose flesh and fat. These fleshings and the trimmings from the hide house are sold as glue stock. The next operation is the important one of loosening the hair from the hide. This is done by soaking in vats of hydrated lime strengthened by sodium sulphate. The hair roots are destroyed and by means of a dull-knifed machine similar to the flesher, the hair is scraped clean. The hair is sold as an important by-product. The hides are at this stage swelled by lime and must be bated to make them soft. Bate is an acid chemical which neutralizes the lime and makes the hides soft and pliable.

The Tanning Operation

Up to this stage this stock is still decomposable

New Finishes Popularize Bird's Eye Maple

Furniture of This Wood is Now in More Demand Owing to the Vogue for Deep Browns

By C. J. La Vallee*

It is quite interesting to notice just now quite a decided trend on the part of furniture makers to use bird's-eye maple once more. This wood was quite largely used and became very popular years ago, but at that time it was not shown in any colors except the purely natural and such delicate shades as the lightest of silver grays and greens.

From the manufacturers' standpoint, the use of the wood at that time was not completely satisfactory because of its tendency to rapidly turn yellow after it was away from the factory only a short time. On this account only the very choicest of woods, both as regards color and figure, could be used. So much care had to be exercised in the selection of the wood that the resulting furniture was very expensive. From the standpoint of the home owner, there was a disadvantage in the use of bird's-eye maple furniture because the very light finishes did not blend in with anything else and one was compelled to either furnish a whole room in bird's-eye maple or not use it at all. These two disadvantages, coupled with the fact that the finer grades of wood were continually getting scarcer, undoubtedly had a far-reaching effect in minimizing the popularity of bird's-eye maple as a furniture wood.

Brown Finish is Much in Demand

Now it appears that there is quite a demand for some of the new and beautiful browns on bird's-eye maple, and since some of this furniture has been brought out and the buying public are finding that such pieces lend themselves to most artistic blending with fumed, the rich shades of brown mahogany, American walnut, etc., there will undoubtedly be a large sale of such furniture. It is apparent that bird's-eye maple finished in the rich, deep browns in vogue at the present time will at once overcome the disadvantages mentioned by the writer, viz., the turning yellow and inability to blend with other pieces, and will enable this most beautiful of American woods to take its place in the scheme of the quiet, toneful and restful home where good taste is displayed.

The wood itself from the standpoint of wood finish manufacturers forms an interesting subject for experimental work as a large variety of color effects can be produced, and with the silky undertone characteristic of this wood form combinations of the greatest beauty. The stains used for this purpose are of a type which will insure permanency of color, viz., the metal alkali and acid stains. We believe that the come-back being shown on bird's-eye maple wood is going to result in its having a permanent place among the native woods used in the making of fine furniture, and it should be welcomed back to its rightful place as a most artistic home furnishing material and should receive the consideration it deserves as a most useful and durable furniture wood.

*President, Marietta Paint and Color Co., Marietta, Ohio.

Have Your Finish Extra Nice

Here's a tip to people makin'
Things of metal or of wood,
You can carry home the bacon
If you have your finish good.
You can make each product pay,
If your finish is O. K.

You may build it like Gibraltar,
Your construction standards high;
Yet the customer will falter
And go somewhere else to buy—
Retail clerks fall down on sales—
Just because your finish fails.

So remember the compelling
Force of filler-varnish-stain.
For your finisher is selling
When he beautifies the grain.
You can always get the price,
With your finish extra nice.

The Marietta Message

Flint Varnish and Color Works Erect a Lacquer and Enamel Plant

In order to cater to the ever increasing demand for lacquers and pyroxylin products in general, the Flint Varnish and Color Works of Canada, Ltd., have erected at West Toronto, Ont., a modern plant fully equipped with the latest machinery and devices for the manufacture of their products from the basic raw materials. This plant will fill a long-felt want in that Canadian trade as, in many instances heretofore, lacquers have had to be imported from other lands.

The Flint line embraces such products as metal lacquers, wood lacquers, bronzing liquids, split leather solutions, waterproof belting cements, and in fact, it is understood they are in a position to match any of the imported articles of this character.

The plant has in addition technical laboratories which are equipped to render such service to their service department as is necessary to demonstrate their products in a practical way to the Canadian manufacturer.

Keep Up-to-Date

The only safety for any business, no matter how successful, is in keeping up to date. "Keep marching," must be the motto. Success keeps step with the time—and times change.

Building up a Demand for Decorated Goods

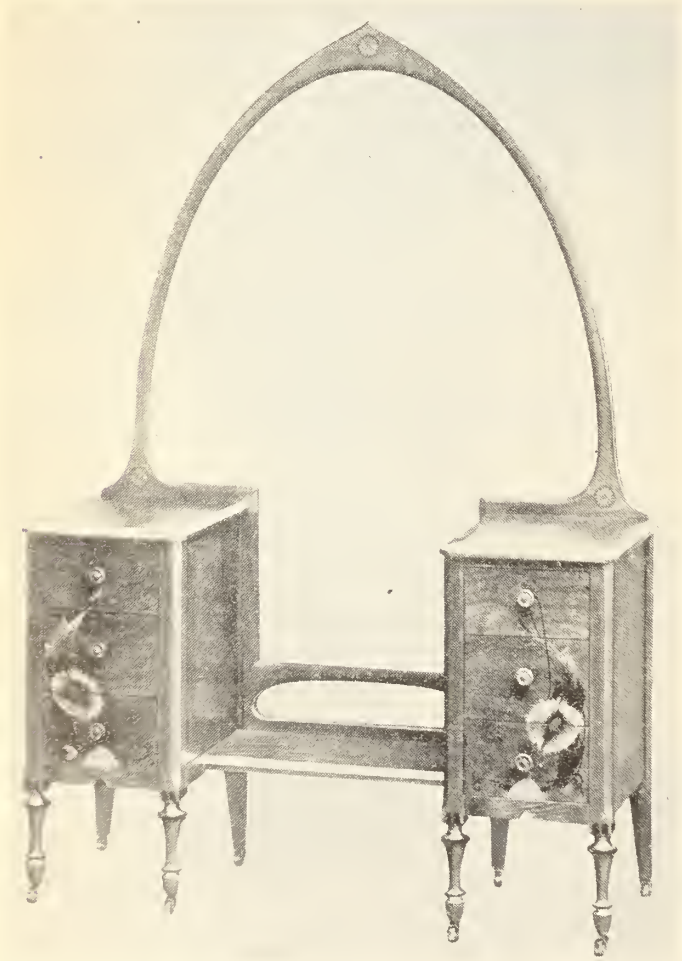
How a Firm Specializing in High-Class Furniture Has Achieved Success—The Finishing Department is a Veritable Art Studio

The vogue for decorative furniture and the appeal which it makes to artistic and discriminate buyers lends special interest to a description of a plant where exceptionally high grade lines of this kind are produced. While the furniture turned out by this plant is of a high artistic order, there are other features of the factory and its organization that are worthy of mention. These will come out as the article proceeds.

In 1916, two men of much experience in building furniture for the other fellow in Jamestown, N. Y., and possessing a splendid appreciation of the vast importance and the great influence of beautiful furniture in the home—two men with an ideal—Oscar R. Pang and Theodore G. Shellberg, organized the Nypenn Furniture Co. The company was established at Warren, Pa., in a small but advantageously located building formerly used for furniture manufacture and now a plant most modernly equipped for every operation from the handling of the raw material to the finished pieces of the woodworker's art.

Nypenn has in the short period of six years become synonymous with good furniture. The company's trade-mark which the workmen religiously live up to is the T-square surmounted by the triangle. The T-square is the tool of the craftsman for building correctly and conscientiously and the triangle emblematic as the apex of achievement. The trade-mark mentioned incidentally as an instance of the thought given the various details of this business.

How to have attained in so comparatively short time a recognized position in the furniture world for the excellency of its product is attributed to the one commanding principle of co-operation. This thought of co-operation is shown in the management's always assuming a most just and liberal attitude towards its employees—a policy which is not only good business acumen but, in some degree, a good manifestation that business is not entirely material but that the character of the men higher up has a most benefical effect on the morale of the worker.



Two pieces of an especially attractive decorated suite made by the Nypenn Furniture Co. They are of antique, grey walnut finish with wide silver bands and gold and black striping. Poppy motif in the decoration illuminated somewhat in the manner of old manuscripts. The draw pulls are especially interesting in that they form an essential unit in the decoration. The overlays on the base "lines" repeat the line of the mirrors, thus making for an harmonious composition.

This attitude as co-workers for a common ideal is practically evidenced by the fact that, without any expense or preliminary examination, all workmen on entering the employ of the company are given at the end of six months, life insurance in sums ranging according to their ages from $500 to $750 which increases each year up to $1,500.

Workers Encouraged to Buy Stock

The encouragement of workmen to buy stock in the company has proven a most effective way to bring about good work and the employer further demonstrates this liberal attitude by giving employees

Building up a Demand for Decorated Goods

(Continued from page 76)

a yearly bonus. All this has made able, loyal and interested workers who naturally reciprocate by each man giving his utmost in quantity and quality of production. Active figures show that the output of the plant is in many instances equal to some with twice the number employed, and the company, appreciating that business is really more than a matter of mere capital and factories, considers this loyalty and interest on the workmen's parts, it's greatest asset.

The great demand for the company's line of merchandise has necessitated the planning of another addition to the plant to be used for the production of the decorated suites and will be the third substantial addition since organization.

This enormous demand also brought about the somewhat forcible realization that this department of the business was not good enough. Thus, at the beginning of the current year Willem Dieperink Langereis was added to the staff as designer and general director. This artist is known throughout the country for his cleverness and originality and his consummate skill in the applied arts. In his various magazine articles on the applied arts and, especially those on furniture, there has always been an eloquent appeal for the artistic and practical.

A number of the reproductions here given and, especially of the Patrician suite, the Nypenn's most recent creation and a magnificent specimen of line and color, will more amply speak for what line and balance imply as applied to furniture, and this suite is truly an embodiment of the company's slogan.

Distinctive Decorative Designs

The past and present successes of the company undoubtedly auger a brilliant future for success is founded on the realization of the fact that employer and employee do not exist independently, but are co-existent and that success or failure must come to each in equal measure.

When the saw begins to burn the wood it means either more set or the front of the teeth should be ground back to get sharp edges on the teeth.

Spread the material you are applying, evenly over the surface; cross diagonally so that it lies even and finish with a light stroke.

A Brand New Finish

"Brown Bird's-Eye Maple"

Featured at the Markets

HAVE you seen this beautiful new finish? Has your foreman obtained the sample panel which will be sent to you absolutely free?

Do not confuse this new shade of rich, warm brown with anything that has been used before. **Brown Bird's-Eye** is the result of a master craftsman's experience and effort. When you have seen it you will know why it has been so enthusiastically received wherever it has been shown.

Bedroom suites, novelty furniture, two-tone effects and decorative panels take on new life when **Brown Bird's-Eye** is used. It is particularly striking for inlays, overlays and the like—wherever a warm, pleasing contrast in color tone is desired.

Better yet—See for yourself. Your finishing house will send you a sample panel immediately upon receipt of your request. Or write to us direct, we will see that you receive a finished sample.

The fact that **Brown Bird's-Eye** can easily be produced by your foreman will appeal to you. Just show him a panel, he will know how it is done. Write or wire today for a sample—sent to you absolutely free.

The Selection of Glues for Joint and Panel Work

Several Grades on the Market With Very Wide Differences—Price is Not a Criterion—Proper Tests Should Govern Glue Purchases

By R. H. Bogue, Ph. D*

Although no set rules can be laid down for the selection of a glue for a given purpose, yet a few general considerations should be borne in mind. Too often a consumer of glue fails to recognize the wide differences that exist in the several grades on the market. What he really wants is the lowest priced glue that will do his work satisfactorily, but his lack of knowledge upon the subject leads him to believe oftentimes that price is the sole factor worth attention, and his work suffers accordingly.

On recognizing his own ignorance upon glue he may put his problems up to the glue salesman and rely upon him to provide him with the proper material. Although most large glue houses employ competent and honest salesmen to handle and distribute their product, yet it must be understood that not all glue salesmen are experts in glue engineering, nor are all salesmen scrupulously conscientious in giving the buyer the best for his money. In short, a consumer who relies entirely upon the salesman is placing himself in a position where he may be sold more expensive glue than he needs; an improper type of glue for the service desired; a poor glue for the price of a good material, or other glue fraudulently described. No injustice is meant to be done the many reputable and competent dealers and salesmen, but not all of these are honest, and not all that are honest are competent. The only safe course for the consumer to follow is to make or have made proper tests upon all material bought, and ascertain that the shipment is as per specifications.

Price Not the Determining Factor

The belief that the price should be the determining factor in glue purchases should be dispelled. A higher priced glue should, as has already been shown, have a much greater covering capacity than a cheaper product, and at the same time produce much stronger joints. These factors must be properly balanced if glue is to be selected efficiently. Under no circumstances should a partially decomposed glue, as revealed by the disagreeable putrid odor, be accepted.

For high class joint work only a good grade of hide glue is used. Although some of the best bone glues may give as good results as an intermediate or low grade of hide glue, it is rarely that large amounts are diverted to such usage. Glues that have been given a ficticious viscosity, as by the addition of alum, should be regarded with suspicion until they have been proved satisfactory. An extraordinarily high viscosity should be compared with the jelly test, and if the former is found to be incommensurate with the latter, a test should be made for ash and alum. An unusually clear glue with high viscosity will often be found to have been clarified with alum. The use of glues with such abnormal viscosities is not ordinarily attended with the best results, for either the glue will be diluted to the consistency at which it is easily applied, and in that case contain actually too small an amount of real glue to make a strong joint, or else it will be applied at the usual percentage of dilution, and in that case be too thick to easily penetrate the pores of the wood, and fail from that reason. If, however, the high viscosity is accompanied by a similarly high jelly strength, such a dilution that will bring the material to a good working condition will not result in a weakened joint.

An abnormally high jelly strength for the viscosity is also undesirable as a rule on account of the rapidity with which such a glue will set. If the glue sets before the joining operation is completed and the pressure applied the joint will be weak. In using such glues it is necessary that the wood be heated to a higher temperature, or that more rapid operation be employed.

The hydrogen ion concentration, or the degree of acidity or alkalinity, should be taken into consideration, as an excessively alkaline glue, pH 9.0 or higher, is usually indicative of overlimed stock which will continue to weaken even after applying to the joint, and an excessively acid glue, pH 3.0 or less, may affect and weaken the fiber of the wood. Between these values, however, there are not likely to be any ill effects noted. The region of pH 4.7 should be avoided, as the viscosity, swelling strength, etc., of the glue are least at this point, but this may easily be corrected by the consumer by the addition of small amounts of acid or alkali. The regions of pH 3.5 or 8.0 are ordinarily most favorable.

If the glue is to be applied by hand the foam need not be considered. If spread by machine, excessive foaming is undesirable. This is ordinarily depressed by the addition of a little fatty matter, but if too large amounts of grease are present a weakening of the joint will result.

Glue for Veneer Work

For veneer work a lower grade of glue may be employed, but a higher viscosity is desirable. This latter is necessary on account of the tendency of a thin liquid to penetrate the pores of the thin sheet of wood and show itself on the opposite surface. The higher viscosity of the liquid used tends to offset this

*Formerly Industrial Fellow of the Mellon Institute of Industrial Research and Research Chemist for Armour & Co., Chicago; now on the staff of Lafayette College.

This article represents a part of the section "Glue as an Adhesive" in the writer's treatise on "The Chemistry and Technology of Gelatin and Glue," published by the McGraw Hill Company of New York.

tendency, and may be secured either by using a higher concentration of the glue, or by employing a glue of a higher viscosity. Since an exceptionally high grade is not necessary, the desired results are very well obtained by using a rather high grade of bone glue and at a somewhat greater concentration. This gives the higher viscosity necessary without increasing the cost. Where penetration does not occur, or when it makes no difference if such does take place, a thinner liquid may be used.

Wide Use for Plywood Panels in Jobbing Shops

Departmental Stores, Hotels, Institutions, Theatres, etc., Employ Vast Quantities for a Large Variety of Purposes—Saves on the Machine Work and Finishing and Decreases Lumber Stocks

By A. W. Williams

One can go into almost any kind of a woodworking plant and find that the owners make use of plywood panels in many ways. They get this material in large sheets, and it is used for drawer bottoms, backs for cupboards, and in innumerable ways. It has in many cases simplified the work of construction in cabinet work, and this applies also to the unlimited assortment of cupboards for commercial and household purposes, of a special nature, that the average town woodworking shop is called on to make.

Take in the case of a cupboard back. Formerly this called for a great deal of work. Rails, called muntins in the trade, had to be tongued and grooved and fitted to the top and bottom of the framing. Panels had to be prepared by resawing or by dressing the lumber down to a thickness, and in many cases by gluing two pieces together before the operation of resawing or planing could be carried out. Then this framed back had to be put in place, which called for a great deal of time to be spent, that is, in comparison with the amount of work involved in putting in a back now.

By the woodworking plant being able to buy large panels in stock sizes, in several different kinds of woods, their work is made very simple where backs and many other parts are concerned. British Columbia fir is undobutedly the most in demand for general purpose work, and if we could see some figures totaling the yearly consumption of this material by woodworking plants we would no doubt get a surprise. It is supplied in several different thicknesses, and many are the uses found for it.

Wide Range of Use for Plywood

The writer was in a woodworking shop recently operated by a large departmental store, and the amount of plywood they consume is amazing. This department is called upon to make all of the fixtures for the company's very large store, and the number and kinds of fixtures to be made are practically endless. The construction of these fixtures, counters, etc., simply resolves itself into a job of making the framing and filling the frames up with panels. Not only are figured wood panels used for the parts of the fixtures that are seen, but thousands of feet of the common class of wood panels are used for inside parts, backs, divisions between drawers to keep material from falling from one drawer into the one underneath it as often happens when drawers are being constantly pulled out and in.

The necessity for these divisions was brought home forcibly to this firm on one occasion when they were about to shift some fixtures from one department to another. They had been used for ladies' waists, and a number of expensive waists had worked their way out of the drawers and dropped down on the floor under the drawers. They were found when the cases were moved, and they were ruined. This decided them on putting the divisions between the drawers. With this form of construction it is difficult for any of the contents of the drawers to work out, and even if they do they cannot get out of the space which the drawer occupies, and they cannot escape observation there as the drawers are removed periodically for inspection.

These divisions increase the use of three ply panels tremendously in this particular shop, and they are only one instance of how new uses are being found continually.

A Boon Where There is Little Equipment

I was in a carpenter shop the other day connected with a large university, and they were quite alive to the possibilities of plywood. They use it extensively, and find it a great boon. In fact I sometimes think it is more of a boon in some of these jobbing shops with a limited amount of machinery than in a really large plant that is fully equipped. Very often the men in these shops would be put to a great deal of trouble to devise a method of construction that could be worked out on the machines at their disposal. For instance, they have no planer. Any work to be planed has either to be sent out to a mill or planed by hand. It will be apparent, therefore, that where they can carry a stock of dressed lumber of a thickness suitable for framing that they have only to rip to a width or cut to length, their work is comparatively easy. It is a simple matter to groove the frames to receive the panels on an ordinary table, and then the panels being obtainable in large squares that will furnish panels of any desired size, makes the work easy.

Another case where I found these panels being made use of recently that was rather interesting was in a theatre. The theatre was being operated by a stock company, and the stage carpenter found the demands for changes of settings quite numerous, and was employing three-ply fir panels to excellent advantage. When I went in to the theatre to see him he was just returning from a nearby planing mill with several fir panels band-sawed to somewhat curious patterns. He was'nt very clear himself as to just what they were for, the designer of the scenery not having explained to him further than furnishing the pattern, but it was evident that plywood was used frequently as a base for scenic effects.

In the department store carpenter shop that I spoke of at the beginning of this article I found them getting out a large quantity of three ply panels recently, that is, they were cutting them to size, and on asking what they were for I was informed that

Wide Use for Plywood Panels in Jobbing Shops

(Continued from page 82)

they were to be used for making suit cases. It seems the suit cases are framed up of three ply stock and then covered with imitation leather.

When asked in what particular manner the use of built-up panels had been of benefit to them in their work the superintendent of this shop said their work now consisted largely of getting out stiles, rails and mouldings, and where formerly their draftsmen had been in the habit of drafting up all sorts of complicated forms of construction they were now conversant with the possibilities of ply panels and were careful to make full use of them.

Formerly some of their designs had called for expensive machine work, these involving the use of numerous small panels. Nearly all of these were "raised," or moulded, on the edges on a shaper. At this time their store was not nearly so large, and the demand for fixtures was limited. They had been able to take care of the work then, but if they were obliged to resort to the same methods of construction, now that their work has increased about ten fold, they would be obliged to carry an immense stock of lumber, and they would require a much bigger shop with a great deal more equipment.

The stock of lumber, comparatively small, that they now have to carry is an important item. In a shop such as they run, being down town where property is expensive the firm has to put it to better use than lumber storage. Therefore, with panels to be obtained from stock from several local houses, they are only obliged to carry a very small stock of lumber. They can usually get their requirements promptly in both lumber and panels.

Cheaper to Finish

I think one of the most telling points this gentleman made in enumerating the advantages of panels was that they save considerable money in finishing. By using large panels without moulded edges, or carvings, they are able to do a great deal of their rubbing with an electric rubbing machine. With the old forms of construction this was out of the question.

The advantage advanced for panels in this particular line of work, will, I think, apply in practically every woodworking shop where general jobbing is done, and summed up, these advantages are a great deal less machine work in the construction of cupboards or fixtures of any kind, less lumber to be carried in stock and less machinery. This last feature applies particularly in connection with a carpenter shop operated in conjunction with a large institution of some kind. Formerly they would have found it necessary to install a complete woodworking shop, whereas now they can turn out a great deal of work, in fact practically everything needed, with no machinery other than a jointer, bandsaw and variety saw table, and very often small bench machines operated from electric light sockets will suffice.

Conflicting Opinions About Cauls

Some Firms Use Aluminum Cauls While Others Find that Wooden Ones Have Fewer Faults—One User Has Adopted a Special Design

By Traveller

I always consider that piano factories, generally speaking, have been in the veneering business longer than any other line of woodworking, and their ideas are, as a rule, worth listening to. There are five piano factories in the city where I live and it occurred to me that it might be of interest to make a round of them to discuss the subject of cauls.

The first of the five is still using wooden cauls, and I asked the superintendent if he used wooden ones by choice or whether he had simply continued to use them instead of trying out any other kind. He informed me that he had tried them all and came back to the wood cauls as having the least number of faults. He said he had spent a good deal of money on aluminum cauls, but soon tired of them. The principal reason for this was that they were compelled to cut down the number of pieces of stock in the press owing to the short time the aluminum cauls would retain the heat.

Another difficulty was to keep sufficient grease on the cauls to prevent the veneer sticking to them. If the cauls were used with too little grease and the glue stuck to them the men would invariably try to remove the glue with a chisel; with disastrous results to the cauls.

This gentleman therefore decided to go back to the wood cauls, but in making this decision he decided to use wood cauls that were somewhat different from those used years ago. He took a lumberman with whom he did considerable business into his confidence and advised him that he wanted to get some very wide poplar boards. His idea was to have cauls without joints, and he got them by paying a pretty steep price for the lumber. At the same time these cauls came out a great deal cheaper than aluminum. The widest were about 23 inches. There was a set of these, and another set about 20 inches and some about 16inches. These boards were all specially selected quarter cut poplar and they certainly made a fine outfit of cauls.

Cauls Specially Treated

These cauls were put through a special course of treatment before being put in use. They were heated thoroughly, after being dressed to an even thickness, and beeswax applied to them. This operation was repeated time after time till the cauls were practically saturated with beeswax. Then instead of using zincs between the veneer and cauls as was a popular custom years ago the wood cauls were used by themselves, and the veneer did not stick to them. These cauls retain the heat better than metal. Metal cauls get red hot almost, and then they cool off very quickly whereas the wood cauls do not get burning hot but retain the heat for a lengthy period. The wood cauls are waxed periodically, and one man was made responsible for keeping them in perfect condition.

No trouble has been experienced with veneer or glue sticking to the cauls. One of the arguments in favor of aluminum cauls is that you can put more stock in the press on account of them being so much thinner than the wood. My informant did not at-

tach much weight to this argument and told me to take notice of the press loads in a nearby plant when I visited it. This I did, and I found that they made a practice of building up the bottom of their press with boards, and that on an average twelve pieces constituted a press load. I enquired if this was all they put in a press at one time and was advised that it was; that they could not take a chance on putting any more stock in on account of the cauls cooling off quickly.

Another thing that I took note of was the number of men they used to put in a press. They employed five men on this work, and when I asked if all these men were necessary I was advised that it had been their experience that it was much safer to use five men so they could get the stock under pressure as quickly as possible.

Fewer Men Required

In the first plant they only used four men, and they seemed to accomplish the work just as effiicently. They may have taken a little longer, but I do not think the extra time required amounted to much, and it was easily set off by the fact that they put more stock in a press, their batches usually being about eighteen pieces.

I was not able to see them putting in a press in any of the other plants, but one of these used wooden cauls and the other two aluminum. The wood cauls used by this concern are the ones they have used for years, but it is significant that these people also experimented with aluminum cauls, although they did not go to the expense of putting in a complete outfit, and they retained their wood cauls.

The arguments they advanced against the aluminum cauls were almost identical with those already recorded. The other two plants using the aluminum cauls had not much to say against them, and little to say for them. They seemed to be in the position of having thrown out the wood cauls and bought the others, and were content to go on using them.

The Advantages of Veneer Re-Drying

By the Merritt Engineering and Sales Co.

Wherever there is gluing of wood veneer, there is call for a machine or a process that will flatten veneer and make it thoroughly dry before it passes into the glue press. Lack of precaution in this respect causes certain failure and the attempt to glue veneer in which the contained moisture is an unknown quantity is attended with uncertainty and danger. The loss and damage arising from the use of imperfectly dried veneer is almost incredible and the remedy is so simple and sure that there is not the slightest excuse for it.

Veneer is not always thoroughly dry when it leaves the mill and in fact, it is better that it should be only "shipping dry." Even though thoroughly dry when shipped it is bound to take up enough moisture from the air to cause trouble by the time it reaches the glue room. The truth of the matter is there should be a final re-drying at the plant where the veneer is used and it should precede the gluing but a day or two.

Some kinds of wood are more sensitive than others to the influence of moisture and cause more trouble in the glue room. This is notably true of gum and several instances have come to our attention in which manufacturers of veneered doors have experienced losses running into carloads, simply because the veneer contained too much moisture and had to be redried. The installation of a plate drier instantly puts an end to trouble of this kind.

The flattening of veneer is also a matter of considerable importance. A sheet that is wrinkled or corrugated does not get an even distribution of glue, the pockets and depressions causing a needless glue consumption that is an important factor in the cost of production. It is often remarked in a gluing-up department, that a consignment of wrinkled veneer eats up glue very much faster than an equal quantity of flat and plate machines have been profitably installed from this one cause alone.

Then again, there is a great deal of veneer broken in the glue press which could easily be saved if given proper treatment in a machine that first sweats and then flattens its product. In this class are included sheets that are corrugated on the ends as well as those containing knots, each one of which causes the veneer to buckle for a considerable distance around it. Many a piece of cross-banding has been saved in a plate machine because in no other way can a knot or a cross-grained piece be brought down flat without splitting.

Finally, the owner of a plate machine is not dependent on any one mill for its supply of veneer. He need only require that the veneer be properly cut, knowing full well that the re-drier can be dependent upon to make the final result absolutely certain.

Action of Glue in a Wood Joint

This greatly enlarged section through a glued joint of plywood illustrates a fact, not generally understood, that the glue uniting two wood surfaces does not lie in a smooth sheet but enters the cell cavities through the open ends on the cut surface and clinches the joint by means of millions of tiny barbs and anchors. The arrow indicates the point

How glue penetrates into wood pores

at which the glue entered the pore to the left of the glue line. The glue-filled pores near the glue line on the right all open on the cut surface at some point and were filled in the same manner, as little or no penetration takes place through the cell walls. Viscosity and pressure must be adjusted to suit the character and number of cells and pores in different kinds of woods to obtain the strongest joint. The photograph was furnished by the U. S. Forest Service.

How Upholstery Leathers are Manufactured

(Continued from page 72)

and if allowed to stand would rot. It is therefore, placed in the tan yard in vats of weak tan liquor. Being near the lumber districts, the Eagle-Ottawa Leather Company can use the hemlock bark tannage which gives a much softer leather than the commercial extract. The liquor is obtainable by pouring steam over great leaches of ground bark and running the resultant liquor through pipes to the storage vats below. The liquors are gradually strengthened and the tannins enter the corium fibres of the hides changing them to an insoluble and imputrescible product. This is the pivotable step in which the character of the goods undergoes permanent change. This step also demonstrates why genuine leather can outlast its imitations. No matter how cleverly applied, the finish of these latter may be, the even penetration of the tannins with chemical and physical actions makes the genuine article something that will wear for years. "As tough as leather" is an axiom.

However, leather cannot alone be tough; it must be soft and pliable as well. After tanning, the hides must be split as the natural thickness would prevent their being of any commercial use except for sole and harness leather. The belt knife splitting machine is one of the most wonderful pieces of modern machinery ever invented. The hides are fitted in between rollers and split by a rotating knife to a required thickness. The top, or grain leather, is the softest and best, so from it are made all our deluxe morocco and dualtone leather. Next comes our Wolverine special machine buffed, which is used for less expensive upholstery. Then the second split, which is used for diners and pad seats in the furniture trade. Next comes the slab or collar split used for horse-collars or a thin grain or buff may be removed from the hide for pocket-books or camera cases. The next cut is the machine buffed followed by the first and second splits. All grains are then retanned and fat-liquored to give softness and pliability. They are then tacked to dry.

Finishing

The leather is now said to be "in the russet" and is carefully sorted before being sent to the finishers. The hides are first given several coats of finish, forming a strong non-crackable pliable film over the surface. This is followed by two coats of paint of the desired shade and luster. These coats are dried in the ovens and then the leather receives a light smoke over-coat. It is crushed by hand to bring out the natural grain and then rubbed carefully with solvent, which removes the upper coat on the folds exposing the under-coat, and leaving the upper coat in the creases. Thus the beautiful dualtone effect is obtained. Hides are then measured and shipped.

The finish on the finest kind of leather that goes on furniture can be ruined by the use of varnishes or furniture polishes, most of which contain solvents that will penetrate the finish of the leather and cause it to become soft and sticky. When you buy leather furniture from your manufacturer. It would be well to insist on a guarantee that the surface coat has a linseed oil finish. What is known as a straight "dope" leather has an offensive order to begin with and will become sticky in a comparatively short time, especially during hot weather.

We suggest the following formula for cleaning upholstery leather: use nothing but castile soap and water. Apply a damp (not wet) cloth to the soap and rub the surface of the leather briskly; next apply a moist cloth without soap; finish by rubbing dry with a clean soft cloth.

How To Reduce Costs

Writing in the Bulletin of the Taylor Society, Wallace Clark outlines a practical plan for reducing losses during a depression. In a period of declining or dull business, there are in every manufacturing plant certain expenditures which must go on, no matter how few orders there are. A skeleton organization must be kept in the shop—the superintendent, foreman, inspectors, truckmen, watchmen and so on. In addition, there are the interest on the investment on land, buildings and equipment, depreciation, taxes, insurance and repairs. All these expenses go on whether there is work or not; they are due to keeping ready for work and are not increased by the acceptance of an order. It is clear, therefore, that these overhead expenses or losses will not be increased by the acceptance of an order at a price which does not cover any of this overhead. The expenses created by the acceptance of a specific order are cost of material, direct labor, power and fuel. It may be stated then that prices can be reduced without increasing losses to a point which covers the cost of material, direct labor, power and fuel, but which does not cover any part of the overhead.

Knowing that he has nothing to lose until he reaches the material-labor-power-fuel cost, the manager begins to lower his quotations and keeps on until he gets the orders. When there is plenty of work ahead, prices should be quoted which will produce profits, but when there is little work to be had, prices should be quoted which will reduce losses.

The Lumber Market

Domestic Woods

The general demand for hardwoods continues on a more satisfactory scale than for some time past. The number of inquiries is steadily increasing and an improvement for the lower ends is noticeable. Woodworking industries are generally quite active, particularly furniture factories, piano firms and phonograph companies. This, of course, is largely attributable to a rush of orders for Christmas specialties. Whether the present activity will continue after the holidays is another question. In the meantime, business in these plants is on a better basis than it has been for some time. Agricultural implement and vehicle firms are also quite busy and a number of them are taking on extra men.

It looks as if those who are anticipating their wants and replenishing their depleted stocks of hardwoods at the present time are showing good judgment and wise foresight. There is bound to be a scarcity of certain grades and thicknesses of dry hardwood during the spring, which will mean a corresponding increase in price. Some firms, who are farsighted, are buying enough to cover their requirements until early next summer.

One deterrent factor at present is the securing of adequate supplies and the distribution of the product. The car shortage at divers points is very acute and there are embargoes at many terminals. Everywhere one goes there is heard a strong arraignment of transportation facilities, and were it not for the congestion and the impossibility of making shipments or getting in supplies, the hardwood situation would be a comparative paradise today to what it has been.

Leading dealers report that there is a good call for hardwoods for the manufacture of interior trim and there is moderate buying on the part of other miscellaneous consumers. Prices on the whole continue firm with an upward tendency. As the season advances the requisitions for hardwood lumber continue to grow more pronounced and the inquiries are broadening out in character. A larger percentage of the latter is also developing into orders. One of the leading officials of a big hardwood producing firm stated recently that business was fully up to normal and the volume of orders was increasing each week. The main trouble was the car situation. There will be a larger stock of birch, elm, maple and ash taken out during the coming winter than there has for some time past.

Birch is steady with a slant toward higher prices in the lower grades. Basswood and ash are fairly firm, especially in thin stock. There is a livelier market for the lower grades in 6/4 and 8/4 in ash than there is in the firsts and seconds. Maple is decidedly active, particularly in 8/4 and 10/4, but it is not easy to secure these thicknesses. 4/4 maple is rather dull at the present time.

Manufacturers, wholesalers and consumers of hardwood are looking forward to a steady trade during the coming year. Confidence is reasserting itself and the great desideratum is stabilization of values. It may be said that, on the whole, the hardwood market has come to its own more during the past few weeks than during the whole of the first six months of 1922. This has, no doubt, been caused by the gradual revival of industrial operations, the gradual consumption of stocks in hand and the firm yet upward trend of values. Spreads in prices are not nearly as wide as they were a few weeks ago, which is a healthy indication of the strengthening influence and growing proportions of the market.

Imported Woods

Through the United States the hardwood market is reported to be in excellent condition, advices from all the chief centres indicating that business is brisk and that orders are plentiful. This cheering news is evident even in markets that a few weeks ago were dull. It appears that the effect of the railroad car shortage is still being felt, on which account deliveries are not as good as they should be. However, the mills are expending every effort in trying to keep up with the volume of orders that are being received. Generally speaking, prices are firm with an upward trend, if anything. Indications, judging by the number of orders, are that the woodworking industry will be pretty busy this winter and right through into next season. Furniture factories in general report prosperity while the millwork operators are not much less enthusiastic although there will tend to be a falling off in this class of work as the building season slackens during the winter. Specific reports from some of the more important centres follow.

Memphis, Tenn.—It is reported that the demand for hardwood lumber and forest products is more active than for a great many months, with all kinds and grades being asked for. Manufacturers of hardwood flooring and furniture are in the market in a large way, the former planning to operate full time for quite a while yet, although there may be a little slackness later on as building decreases. The furniture manufacturers find themselves very busy and are in the market for considerable quantities of lumber. The car shortage is still holding up delivery and buyers seem quite willing to pay premiums to ensure prompt shipment. Prices are firm with an upward tendency.

Evansville, Ind.—Exceptionally good market conditions are reported in the Evansville district, the demand for certain grades of lumber having increased. The outlook for business is considered very good although the car shortage is still troublesome and in the opinion of lumbermen not likely to improve for some time. The furniture manufacturers are in the market for considerable lumber and indeed these plants have been operating overtime in order to catch up with the orders that were placed at the last Evansville furniture market. The belief is expressed that 1923 will be a better trade year than the present one for all furniture manufacturers.

Louisville, Ky.—An active demand for all lines of forest products is reported. All woods seem to be moving well and prices are either holding firm or advancing slightly. The hardwood flooring trade is buying freely and the same is true of the interior trim market. The furniture men, too, seem to be buying quite freely. As in other centres, the car shortage is a troublesome feature.

The salesman who takes pains to satisy the small customer lays the foundation for selling the big customer next day.

News of the Trade

Scott Lumber Co. Ltd., Port Arthur, Ont., is a new concern incorporated with a provincial charter to manufacture all kinds of wood products. Capital $50,000.

European Furnishing Fabrics, Ltd., Toronto, have been granted a federal charter to act as agents in Canada for European commercial houses. Capital $250,000.

Wm. Rutherford & Sons Co. Ltd., Montreal, have secured the millwork contract for 24 residences on Oxford Avenue, Montreal, to cost $200,000.

Harris Box & Card Co. Ltd., Sherbrooke, Que., was recently granted a federal charter to manufacture boxes and cartons. Capital $90,000.

Elgin Davenport Co. Ltd., Toronto, is a new organization incorporated with a capital of $40,000, to manufacture and market all kinds of furniture.

B. F. Sturtevant Co. of Canada Limited, makers of dry kilns and fan systems have increased their capital from $50,000 to $200,000.

Tweedale Co. Ltd., Montreal, is a new organization with federal charter to manufacture and market trucks, aeroplanes, automobiles and other vehicles.

Adjustable Dress Form Co., 14 Millstone Lane, Toronto, suffered a loss by fire of about $30,000. The firm manufactured wooden dress forms, coat hangers and other such articles.

Acme Sash & Door Co. Ltd., St. Boniface, Man., were recently granted the millwork contract for the new office building for dentists and physicians, at Winnipeg, to cost $100,000.

J. A. Straith, president and general manager of the Standard Paint & Varnish Co., Windsor, Ont., is convalescing after being badly bruised and shaken up in an automobile accident recently.

Merritt Bros.' basket factory log-yard, Grimsby, Ont., was the scene of a fatal accident recently when A. Grant, an employee, was crushed to death by large logs rolling from a pile nine feet high. Deceased was 35 years of age.

W. H. Glide, a well known carriage maker, recently opened a business in this line at Sunderland, Ont. Mr. Glide has been in the business of carriage making for the past 50 years.

A. L. Little, late of Jones Hardwood Co., Boston, Mass., has joined the staff of Edward Clark & Sons, Toronto, and will look after their shipping interests in Quebec and the East.

The ratepayers of Huntsville, Ont., recently endorsed a by-law granting the Muskoka Wood Mfg. Co., a ten year fixed assessment on their new flooring plant. It will be remembered that the entire plant of the company was burned to the ground last summer.

The Duncan Lumber Co. Ltd., Vancouver, B. C., has opened an office at 222 Craig St. W., Montreal. The company is represented by J. F. Forman, formerly with the Canada Car & Foundry Co. Mr. Forman also represents the Hugh MacLean Lumber Co., of Buffalo.

The firm of Hollowell & Schofield, toy manufacturers of North Bayout, have recently dissolved partnership. A. A. Johnston, having purchased the interest of T. Schofield, the firm is now known as Hollowell & Johnston, sash and door manufacturers.

Car building prospects in Canada look extremely favorable as the Canadian railways are in need of more rolling stock. The consolidation of the Government lines in the Canadian National System is considered a preliminary to the introduction of more rolling stock in the interests of more efficiency and larger carrying capacity.

W. J. Crockford & Co., has recently opened a factory at Orillia, Ont., known as the Orillia Clothes Pin Co., manufacturing 4 inch round clothes pins. The factory is very thoroughly equipped with all the necessary machinery for manufacturing this product on a large scale and business is very good at the present time.

Edmund Hind, manager of the Edmund Hind Lumber Co. Ltd., who passed away recently in Toronto, enjoyed the esteem of a large circle of friends. A comparatively young man of 47 years, he nevertheless had a wide experience in the lumber business. For some time he was with lumber firms in North Tonawanda, N. Y., and later was manager for Smith, Fassett & Co., at Charlton, Ont.

A provincial charter has been granted the Georgetown Lumber Company, with an authorized capital stock of $100,000, and headquarters in Georgetown, Ont. The incorporators of the company are Messrs. Morris Saxe, W. H. Kenter and Albert D Tost. The company is authorized to conduct a general lumber and woodworking business.

Chas. Johnson, who has been manager of the Rochester Yard of Mowbray & Robinson Lumber Co., of Cincinnati, and is well known in Canada, has purchased the Rochester yard. He will carry on under the name of Charles Johnson. Mr. Johnson is a brother of J. R. Johnson, wholesale lumber dealer at Toronto.

O. Pritchard, of Orillia, Ont., well known to the woodworking trade, being in this business for many years, has opened a factory known as the Toy & Woodenware Factory of Orillia, the products including clothes hangers, childrens' sleighs, rocking horses, clothes horses and store display fixtures. Business is reported very good at present.

Fire completely destroyed the planing mill of the James T. Gilchrist Lumber Co., Gladstone Ave., Torronto, recently, causing a loss of $10,000. Some of the machinery equipment was destroyed by the flames, but the greater part of it escaped. The firm is making preparations to rebuild, but are as yet undecided upon the class of construction.

Edward Clark, head of the firm Edward Clark & Sons, Toronto, specialists in Birch, died recently in his 75th year at St. Catharines, Ont. The late Mr Clark was born in Hull, Eng., and came to this country with his parents at the age of six. Farming was his first occupation, but later he established a sawmill in connection with his farm. From then on he was interested in the lumber industry and 25 years ago he established the wholesale business in Hamilton, Ont., which bears his name. Later he moved his headquarters to Toronto.

A charter has recently been granted B. W. Lockhart, Limited, Moncton, N. B., which firm has taken over the plant operated for a number of years by the Paul Lea Co. The B. W. Lockhart, Limited, will specialize in sash and doors and are dealers in spruce, pine and B. C. fir lumber. The firm also operates a planing mill and turns out hardwood flooring.

Operating lumber and limit holders from various parts of Ontario recently waited upon Premier Drury in regard to the retention of the Doyle Rule as the scale measurement in the industry. The premier said that while he did not see eye to eye with all arguments presented on the measurement question, he approached the problem with an open mind. He assured the deputation, however, that the computation basis on existing contracts would not be changed except by mutual consent.

Peter Armstrong, Hamilton, Ont., who for many years

Uniform Lumber Means Greatest Satisfaction To The User!

You no doubt have experienced the expense, loss of time, and loss of materials, caused by the use of improperly cured, wrongly graded, and carelessly handled hardwood.

Kraetzer-Cured Lumber is absolutely uniform in quality, properly graded, and every board plainly marked, showing the grade. To show our faith in Kraetzer-Cured products, every board is stamped with our brand.

THE KRAETZER-CURED LUMBER CO.

Because of our unusual facilities we control the lumber from the virgin growth to the time it is loaded on the cars and shipped to you.

When you have once used Kraetzer-Cured Lumber you will not be satisfied with the ordinary kind. Read the eight important reasons why Kraetzer-Cured Gum is used by thousands with such satisfactory results. It will give the same results to you.

Kraetzer-Cured Lumber is of the very best quality, carefully handled by all departments. Every step in this process is taken with the idea of producing uniform high grade hardwood that w ill give maximum service in your hands.

In addition to Kraetzer-Cured Gum, we can furnish Oak, Ash and other Southern Hardwoods.

The Kraetzer-Cured Lumber Co.

GENERAL OFFICE: GREENWOOD, MISS.

Band Mills: Greenwood, Miss., Moorehead, Miss. Leflore, Miss.

You Should Use KRAETZER-CURED GUMWOOD *Because:-*

1. It is STRAIGHT and FLAT, free from the warp and twist usually encountered in untreated stock.
2. It is BRIGHT and will satisfactorily take any finish.
3. It is free from dote or rot—the sap and gums are eliminated by the steaming process, and fermentation and decomposition are thus prevented.
4. Through the elimination of stain and decomposition, it possesses greater strength and longer life.
5. It contains only atmospheric moisture, enabling it to be used for many purposes without kiln drying.
6. When kiln drying is necessary, this can be done in much less time and with more satisfactory results.
7. It is uniform and dependable. One car like another, grade and measurement what it should be—no time w a s t e d in reporting complaints or shortages, no delays or interference with factory schedules because of holding lumber for adjustments.
8. It is the most economical lumber available. It will satisfactorily answer any requirements expected of materially higher priced woods. Join our little army of satisfied users, and just as peace is about to supplant war, let peace of mind take the place of the warfare and worries that usually beset the user of lumber.

We're proud of this product —that's why.

conducted a carriage factory on Mary St., recently passed away.

Grace Invalid Bed Chair Co. Ltd., Toronto, is a recent incorporation.

London Shipping Containers, Ltd., London, Ont., are preparing plans for a new factory at a cost of $50,000.

Brown & Rutherford, Winnipeg, Man., recently secured the millwork contract for a new skating rink at Winnipeg, to cost $75,000.

The Atlas broom plant has been moved from Springfield to St. Thomas, Ont. Adequate housing accommodation for the employees was lacking in the former town.

Muskoka Wood Mfg. Co., Huntsville, Ont., have started excavation for the building of a dry kiln. The building will be one storey 151 x 60 feet.

Carriage Factories, Limited, Montreal, for the year ended July 31, 1922, showed a deficit on the financial statement of $467,467.

Leduc & Fils, Limited, Beauharnois, P. Q., is a new organization incorporated with a provincial charter ao manufacture and market sashes, doors and other wood products. Capital $49,000.

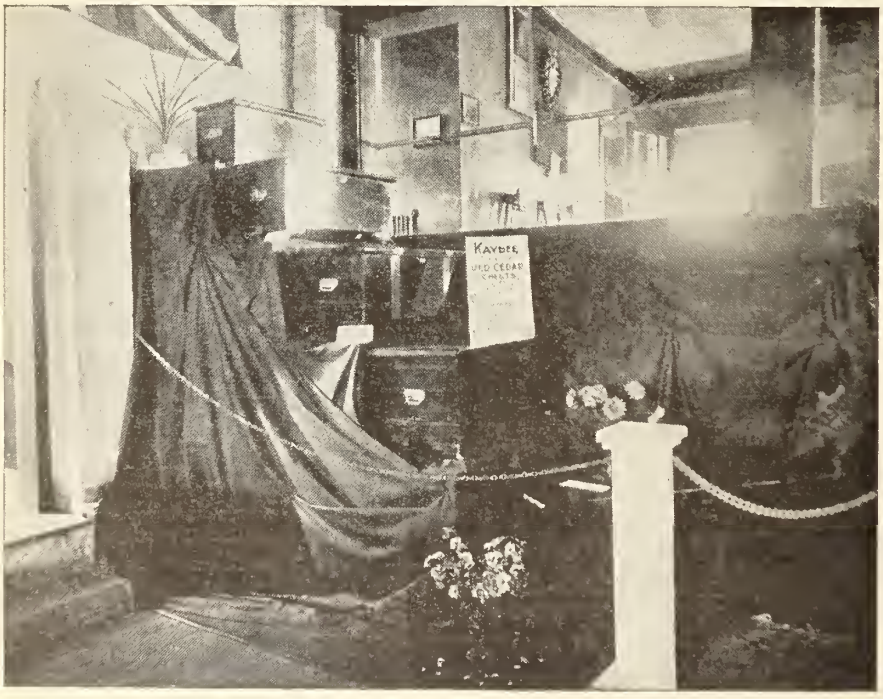
Jean Baptiste Tasse, well known carriage manufacturer of Ottawa, passed away recently in his 79th year. During his career, deceased was employed by Joseph Duford, F. H. Plant, Limited, and the Ottawa Car Manufacturing Co.

Ernest T Lewis, Vancouver, widely known organ building expert on the coast, disappeared after being treated in the General Hospital for nerve trouble. The disappearance was solved recently when the man's body was washed up on the beach in that city.

J. H. McDonald and R. L. Cliff, both of the B. C. Manufacturing Co., box makers, New Westminster, B. C., recently sailed for Australia with a view to enquiring at first hand into the market for boxes and shooks. New Zealand is shipping white pine into Australia in return for hardwood under the new reciprocity agreement between the two colonies.

Keenan Bros., Owen Sound, Ont., sawmillers and woodworkers, recently purchased the property and equipment of Rixon-Ainsley-Stoddart Co. Ltd., Owen Sound. The Keenan people intend scrapping the mill equipment and using the property for storage purposes. The Keenan holdings have now large frontages on the east side of the bay where the Eureka Refrigerator Co., and the Keenan Woodenware plants are located.

The training of apprentices for planing mills and woodworking plants was a subject that was discussed with interest at the recent annual convention of the National Retail Lumber Dealers' Associatiin, held at Cleveland, Ohio. Frank S. Dickey, of the Pittsburgh Lumbermen's Club, spoke on the subject and said that partly due to trade unions and partly due to parents encouraging their sons to follow "white collar" jobs, the trade was slowly being starved. In Pittsburgh and Chicago the problem is being combatted by establishing training schools under proper conditions to encourage an appreciation of the industry.



A pyramid of red cedar chests shown by the Keenan Woodenware Co., of Owen Sound, at a recent Made-in-Owen Sound Exhibit. The display aroused much interest.

Perkins Glue Company Expands

General good conditions prevailing in the wood using industries have reflected in such increased business for the Perkins Glue Company that it has again increased the manufacturing capacity at its plant in Lansdale, Pa. Announcement comes from the sales office in South Bend, Indiana, that the sales of its well known brand of vegetable glue for 1922 are exceeding the sales of any other year in the history of the company.

A mill with plenty of room to move the stuff from machine to machine saves a great deal of useless labor.

General Woodworking Trade Mart

Quick Action Section

Equipment Materials Employment

Position Wanted

EFFICIENCY ENGINEER—administration, production and cost specialist. At present on re-organization large sash, door and general woodworking concern in Eastern Canada. Will be open for an executive engagement on or about 1st January, 1923.

This is your opportunity to secure the services of a high class man at a moderate salary. Willing to go anywhere, preferably Ontario. Highest references. Box 147, Canadian Woodworker, Toronto. 11

For Sale

Rip-Saw, hand feed, Cast Iron Table 36″ x 55½″ with Counter shaft, built by T. Ballantyne & Co. Ltd., Preston, Ont. Also—a Two Spindle Shaper, Spindles 1⅛″ diam. and 18″ on centre, Wood Table 36″ x 48″, Cast Iron Frame and Countershaft; made by Cant Gourlay & Co., Galt, Ont.

Both machines are in first class condition and will give many years of good service. Low prices for Quick Sale.

OTTERVILLE MFG. CO. LTD.,
11 Otterville, Ont.

GOOD VALUES

Subject to Prior Sale

Band Resaw, Connell & Dengler, 54 and 60 inch.
Band Rip Saw, Yates No. 281.
Circular Saw Mill, Hoosier Pony.
Circular Resaw, 30″ and 44″.
Dowel Machine, Clement.
Dowel Gluer and Driver, E. B. Hayes.
Jointer, Falls Machine Co. under cut 24″.
Jointers, 12″, 16″, 24″.
Jointer, Diehl, Continuous Feed.
Lathe, Back Knife, Clement 40″.
Matcher, American No. 229 hardwood.
Matcher, Berlin No. 94, 15″ x 6″.
Moulder, Woods 10 and 12″ inside.
Moulder, American 7″ and 10″ 4 side.
Planers, all sizes, single and double.
Sander, endless bed, 48″ H. B. Smith.
Sander, Moore Machine Co. belt.
Sanders, Berlin 36″, 42″, 48″ and 60″.
Sander, Clement Belt roller table.
Saws, Berlin Double Cross Cut.
1—15 x 4—Four side McGregor Gourlay Matcher.

Woodworking Machinery Co., of Buffalo,
54 Mechanic St.,
Buffalo, N. Y.
10 T.f.

For Sale

Linderman Jointer with cut off saw. Shop Number 265 but this does not represent type of machine as has been rebuilt; is up-to-date and first class, has all attachments. Takes stock up to 72″. Also Fay and Egan Band Rip-saw No. 202, First class condition. Diameter wheel 42″, width of wheel 4″. Tight and loose pulleys, self feeding attachment. Equipment includes swedge, side dresser, power band saw grinder, and brazing clamp. Both these machines can be bought right. Address Box 145, Canadian Woodworker, Toronto. 10-11

Machinery for Sale

1–16″	Buzz Planer (C.M.G.).
1	Chain Mortizer (New Britton).
	Circulator Saw Grinder (Hart Cor.).
3	Head, Hayes sticker 6″.
1–30″	Planer knife grinder (Hart Cor.).
1–20″	Drill.
1	Blind Slat Machine (M.C.G.).
1	Door Clamp.
1–36″	Band Saw (Ballantyne).
1	Rivetting Machine High Speed Hammer Co.
1	Chain Feed Box Board Matcher (C.M.G.).
1	Sash relisher & Mortiser (C.M.G.)
1 Ft.	Mitering Machine.
1	McGregor Gourlay Tenoning Machine.
1	Knight Jig Saw.
1–75	Horse Power Wheelock Engine.
1	Power Mortiser (McGregor & Gourlay).
1	Swing Saw (Goldie & McCullough).
1	Blind Wiring Machine (McGregor).
1	Planer & Matcher (Clarke & Deening).
1 No.	118 Inside Moulder (Berlin).
1	Veneer Press 6 section of 3 screws each (Francis).
1–4	Head sticker 6″ (Greenlie).
1	Saw table (Jackson & Cochrane & Co.).

10-12 E.o.1. Montreal.

Hardwood Institute Starts Engineering Work

The services of Frederick F. Murray have been secured to administer the engineering needs of the Hardwood Manufacturers Institute's program.

Mr. Murray is a graduate of Stevens Institute of Technology, Hoboken, N. J., where he was awarded the coveted degree of Mechanical Engineer.

Mr. Murray is a member of the American Society of Mechanical Engineers and has been active in the affairs of its Forest Products Division.

After a period of employment by the Government in the Ordinance Department, and later in Government construction work.

It is believed that Mr. Murray's training, and particularly the study that he has already made of the lumber industry from an engineering standpoint, admirably fits him for the position with which he is now entrusted.

Concerning the work immediately before the Institute the comprehensive program outlined by Mr. Murray comprises the following:—

A—Complete listing and analysis of hardwood species under consideration, with normal annual production in feet by gades, also general sizes in so far as possible and normal basis sale value by species, grades and general sizes, to provide a working outline of the existing elements of hardwood production.

B—Complete engineer's investigation of industries consuming that production, to involve:

(1) The measure of importance of these industries, and the relative importance of each industry.

(2) Analysis of each industry tracing thoroughly so as to prepare a list of specific articles or classes of articles manufactured by which might be called an individual industry.

(3) A comparison of factory methods in manufacturing these specific articles or classes of articles in the individual industry at its principal manufacturing centers, by both its large and small institutions, in order to determine the variable factors present—wood species used, grades used, sizes and any other variables in specifications looking always for the relation between raw stock and finished product.

(4) As a result of this analysis to determine within as exact limits as possible, the best sawmill and factory practice to attain the best realization—this will involve co-operative study between the manufacturer of hardwoods and the consuming industries and a thorough application of the economics of the hardwood as a whole.

(5) Experimentation and research to establish new utilities for hardwoods, particularly for wayward species overcoming ill-founded prejudice and strengthening utility of grades and species not enjoying full measure of use.

Just how this work will be carried out is a matter now being outlined. Mr. Murray says the operation will largely be determined by a study of reliable data already available and the selection of a program which will contribute most largely to both speed and accuracy. As this work progresses Mr. Murray believes its findings will be both illuminating and convincing to the extreme and that accomplishment of the work will be most gratifying expedited by the thorough co-operation of all hardwood consuming industries.

Business Paper Fundamentals Taught by Daily Newspapers

GLANCE through the pages of any great Daily Newspaper and notice how it tends toward Business Paper practice.

Here is a building section, there an electrical department, again columns of interest to wholesaler, a lumber page, a theatrical page, a sporting page—and next to each you find the advertising relative to the subject in question.

Watch the reader turn to the department in which he is most interested—where the advertising is to be found which will be most likely to appeal to him. So with the business man—as a time-saver, he takes up his business paper to learn the latest developments in his special field. Other publications have but a casual interest for him—because they broaden his general knowledge or afford mental relaxation—but it's the business publication he desires, and requires, when he's thinking of business only. He knows that the business paper will give him the very facts he needs—briefly and **reliably**—in both editorial and advertising pages.

To advertise in business publications places your products before such business men at a time when they're thinking of business.

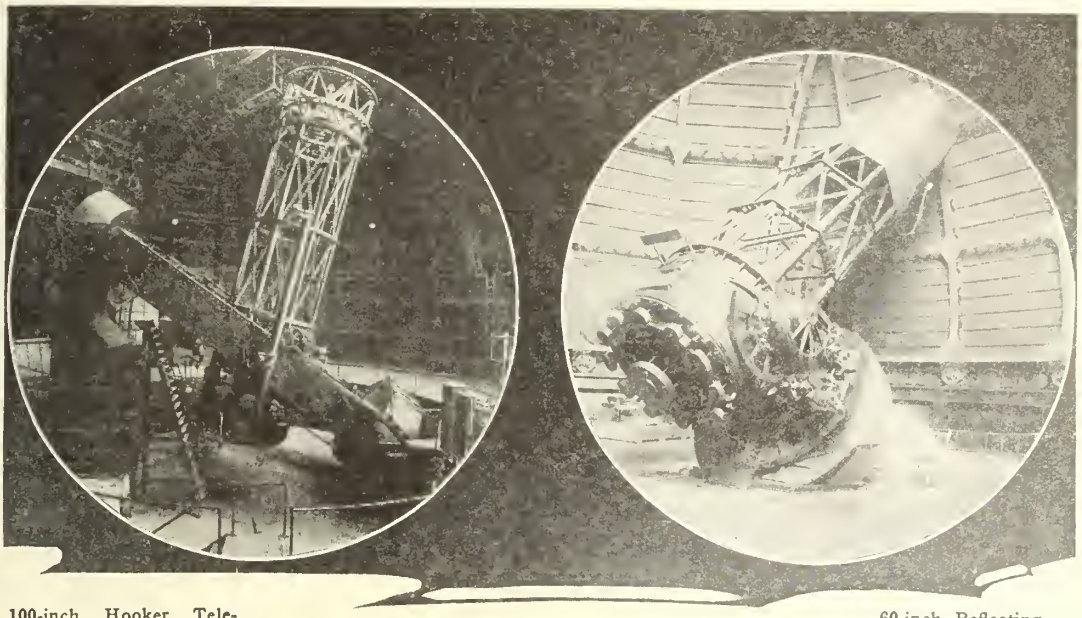
SKF



100-inch Hooker Telescope with Cassegrain spectrograph.

60-inch Reflecting Telescope from the West

The World's Largest Telescope
—*Weight 650 Tons*—Ball Bearing Equipped

Only 50 H.P.—divided between 40 small motors—is required to operate the great 100-inch telescope of the Mount Wilson Observatory—the largest in the world.

The massive 550-ton dome, mounted on 28 ball-bearing equipped trucks, responds to the traction of two small 7½ H.P. motors. Altogether, over 200 **SKF** marked ball-bearings support the dome and the telescope's 100 tons of moving parts.

The companion of this powerful instrument, a 60-inch telescope—likewise at Mount Wilson—is also equipped with **SKF** marked ball bearings.

The fact that ball bearings are very accurate, practically frictionless and show no appreciable wear, contributes much towards maintaining the delicate movement and ease of adjustment so essential where millions of miles are measured by a mere fraction of an inch.

What ball bearings accomplish under these extraordinary conditions is a good indication of their value in the commoner machines of industry and science.

CANADIAN **SKF** COMPANY, LIMITED

What Makes A Garnet Paper Successful?

THE successful performance of any garnet paper is read in the increased production it gives; is noted in the superior finish it produces; it is written in the records of lowered sanding costs.

In hundreds of plants Carborundum Brand Garnet Paper is giving just such sanding results, enabling the sanders to keep production up where it should be—giving a smooth, uniform, scratchless finish—standing up to the work without dulling or filling—and thus keeping down sanding costs.

You would expect such results from a garnet paper that is made right—that has a strong, durable, flexible backing of the best rope stock—that is coated with the highest grade of glue and the hardest, sharpest of all garnet, the North River Garnet.

The Carborundum Company, Niagara Falls, N. Y., U. S. A.

The Canadian Appraisal Co. Limited

The Pioneer Appraisal Organization of Canada

Established 1905

"An adjustment of fire insurance in accordance with existing values is a universal necessity. Many people who now believe that they are properly covered against the fire risk are, in reality, inadequately covered. Morever, realization of these facts is by no means general."

The Chronicle

Over 85% of the appraisals made during the past fifteen years of Canadian manufacturing and industrial properties have been carried out by us, aggregating some 5.000. properties, and include over 250 lumber and woodworking plants.

Correspondence invited

Morgan No. 6 Nailing Machine

MORGAN
NAILING MACHINES

Used in Nailing Wooden Toys

Many manufacturers of American Wooden Toys use our machines for driving 5/8" to 1 1/8" nails. Machines are adjustable in operation and can be adapted to any kind of nailing work.

If you are driving nails by hand, in making boxes, crates, toys, any woodenware articles, figure the cost. It is expensive.

Then send us samples of your work. Get an estimate of the cost of nailing on a Morgan Nailing Machine. Compare the figures. We'll leave the rest to your judgment.

Send us your nailing problems. We shall be pleased to give them our careful consideration and advise you regarding equipment for handling them. We invite your inquiry.

Morgan Machine Company
Rochester, N. Y.

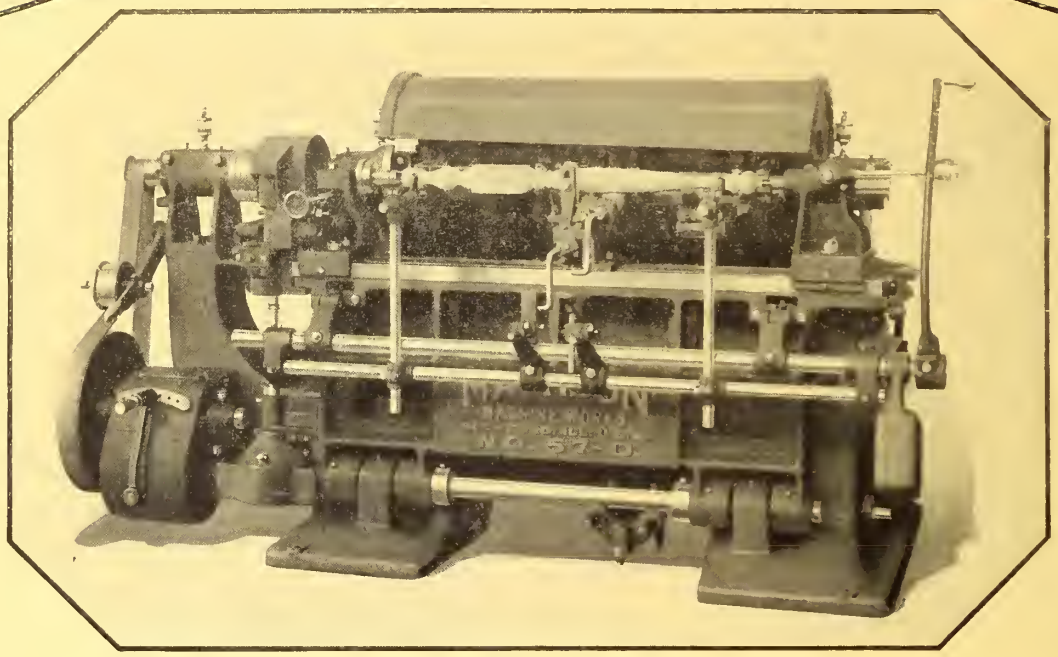
MATTISON



The Result of Continuous Development

The newly designed Model D Mattison Automatic Shaping Lathe satisfies every requirement of modern production in turned work. It is heavier where added weight is an advantage. Its operation is faster and more convenient. Workholding devices have been simplified to facilitate changes and adjustments. Head stock gears are permanently adjusted at factory and are never disturbed, thus eliminating undue wear. Main bearings are larger with an improved lubricating system. These are only a few of the important refinements which our twenty-five years' experience in building the Standard Machine Turner have proven worth while.

Even though you now have an old style turning machine in operation it will pay you to investigate the production possibilities of this New Model.

Ask for Bulletin Describing the New Features in Detail.

FIRE!

IN YOUR FINISHING ROOM

What Would it Mean to You?

Fire comes suddenly and without warning to those who are unprepared. It may destroy the work of years in a few short hours. Can you afford to take these chances? The highly inflammable nature of your finishing-room materials makes your fire risk doubly dangerous.
Many buildings have escaped total destruction only because the fire was confined to the room where it started, by the Gyproc Wall Board used in its building. These experiences have led many others to secure the same protection. One factory building this past summer was struck by lightning and was not destroyed, Gyproc was used on the roof in place of wood sheathing.

GYPROC

WALLBOARD

is in reality a large, strong sheet of pure Gypsum Rock. It is the only wall board that is fireproof, yet it costs no more than others. Gyproc Wall Board has received the endorsation of the fire chiefs of Canadian cities and towns. Its fire-proofing qualities are officially recognized by the Fire Underwriters Association in the reduced insurance premiums on buildings where it is used. With this feature it combines perfect insulation, permanence, utility and economy.
Let us show you what it can do for you.

Take the Word of Men Who Know About Drying Costs

Send for this book today

THERE'S only one way for you to be absolutely sure about the savings in Cutler drying methods **before** using Cutler Kilns yourself—and that is, to get the experience of men who already know by actual use what Cutler **has done** for them.

Every Cutler user has given us his record of results with the most enthusiastic endorsement. To some the lower cost of fewer kilns was Cutler's greatest value! To others, cutting the drying time in half was the real profit-making factor. To still others, the uniform high quality of Cutler dried lumber, was its strongest point.

So, from all these we have selected a dozen letters, signed by men you probably know, and have put them in a little book titled "Better Drying in Half the Time." You can bank on the statements of those men and you should read them without fail before buying new kilns or repairing your old ones.

Send for your copy of "Better Drying in Half the Time" today. Cutler economy starts the minute you close the door on your first load.

All essential features of Cutler Kilns are fully protected by mechanical and process patents granted and pending.

Dry Kiln Department.

CUTLER DESK COMPANY

Dept. F. Buffalo, N.Y.

Cutler KILNS

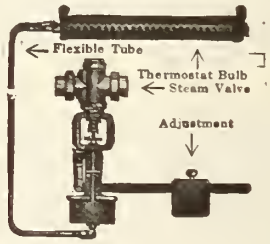
Better drying in half the time

The Certain Method of Controlling Heat Temperature is the POWERS *Method*

You secure the best service possible, when you install Powers Specialties on your hot water tanks, shower baths, in varnish rooms, on glue kettles, dryers, and any manufacturing process where heat is a factor.

The Powers Automatic Heat Regulator is the "Tireless Watcher" on any process requiring accurate temperature to assure perfect results.

The Powers Regulator No. 15



This Regulator is designed for the control of air temperature in drying rooms of all kinds. Can be stepped up or down at will. Easily installed. Entirely automatic, reliable and accurate.

Ask for Bulletin 138.

Adjusted to desired temperature, it will maintain that temperature without variation, and calls for no further adjustment.

Powers Heat Regulators save labor, save material, and insure safety and satisfactory results wherever installed.

Their principal value lies in simplicity of construction, ease of installation, and long dependable service.

Let us prove our claims in your own plant, at our risk.

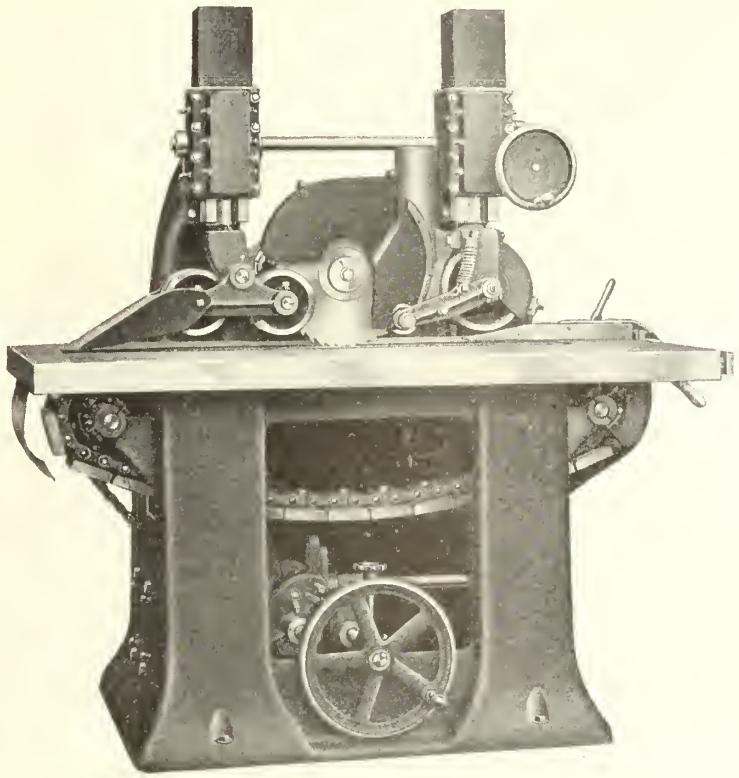
(1859)



A Saw of Economy and Production

is the straight Edging and Jointing Saw, because—it is not necessary to allow 3/8" to 1/2" for straightening purposes. Stock cut on the Edging saw is so straight and accurate that pieces may be glued without further straightening.

This saw rips an absolutely straight line without the use of a guide. Stock once started thru at any angle holds that position until the cut is finished. It is not confined to light stuff, as two inch or four inch birch can be handled to good advantage.

The Straight Edging Saw, as a rule will do as much work as three ordinary hand feed machines. What a saving this means in labor.

The superintendent of a large plant said. "We have two of these modern Straight Edging and Jointing Saws and are particularly well pleased with them, as we get wonderful results. When we first installed these saws, we had six hand rippers and one old type self-feed ripsaw. We put out all these machines and we get the work done just the same with the two Straight Edging and Jointing Saws. The stock is always straight, and I think I am safe in saying that this machine has paid for itself each year. I certainly would not like to run a woodworking plant without one.

If you would like further data on this machine, do not hesitate to write us, we'll gladly send you circular which outlines fully our Type G2 Edging and Jointing Saw.

P. B. Yates Machine Co. Ltd.

Hamilton - Ontario

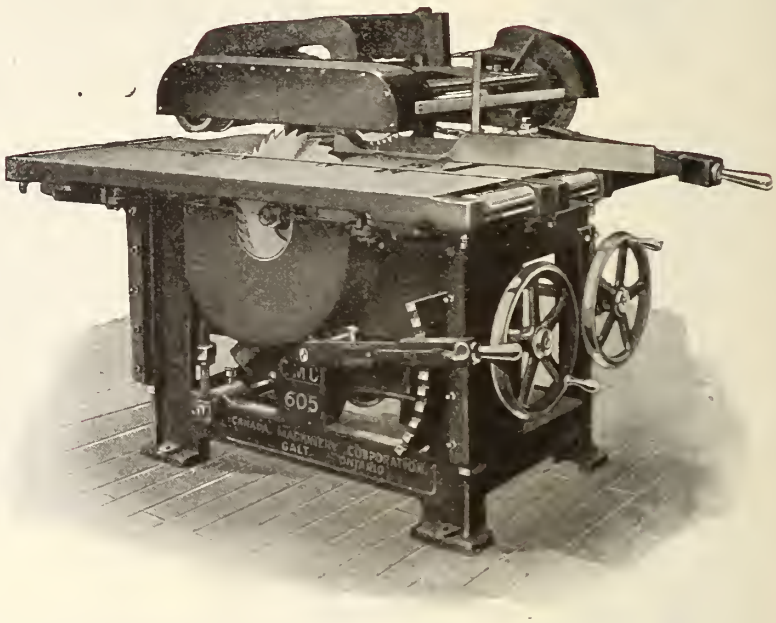
"CUSTOMER'S PROFITS Our First Concern"

We know that if we produce such machines as will give a customer greater facilities; that will reduce his cost of production; will increase his output and protect his employees from accident and body wrecking toil, we can be assured of his patronage.

The 605 Self feed Rip Saw is a profit maker

It will save more lumber
It will save more time
It will save more power
It will save more labor
and will
Do more work
Do better work
Give longer service
and better satisfaction

Than any other self feed saw on the market.



The 605 Self Feed Saw is selling Fast—It is one of

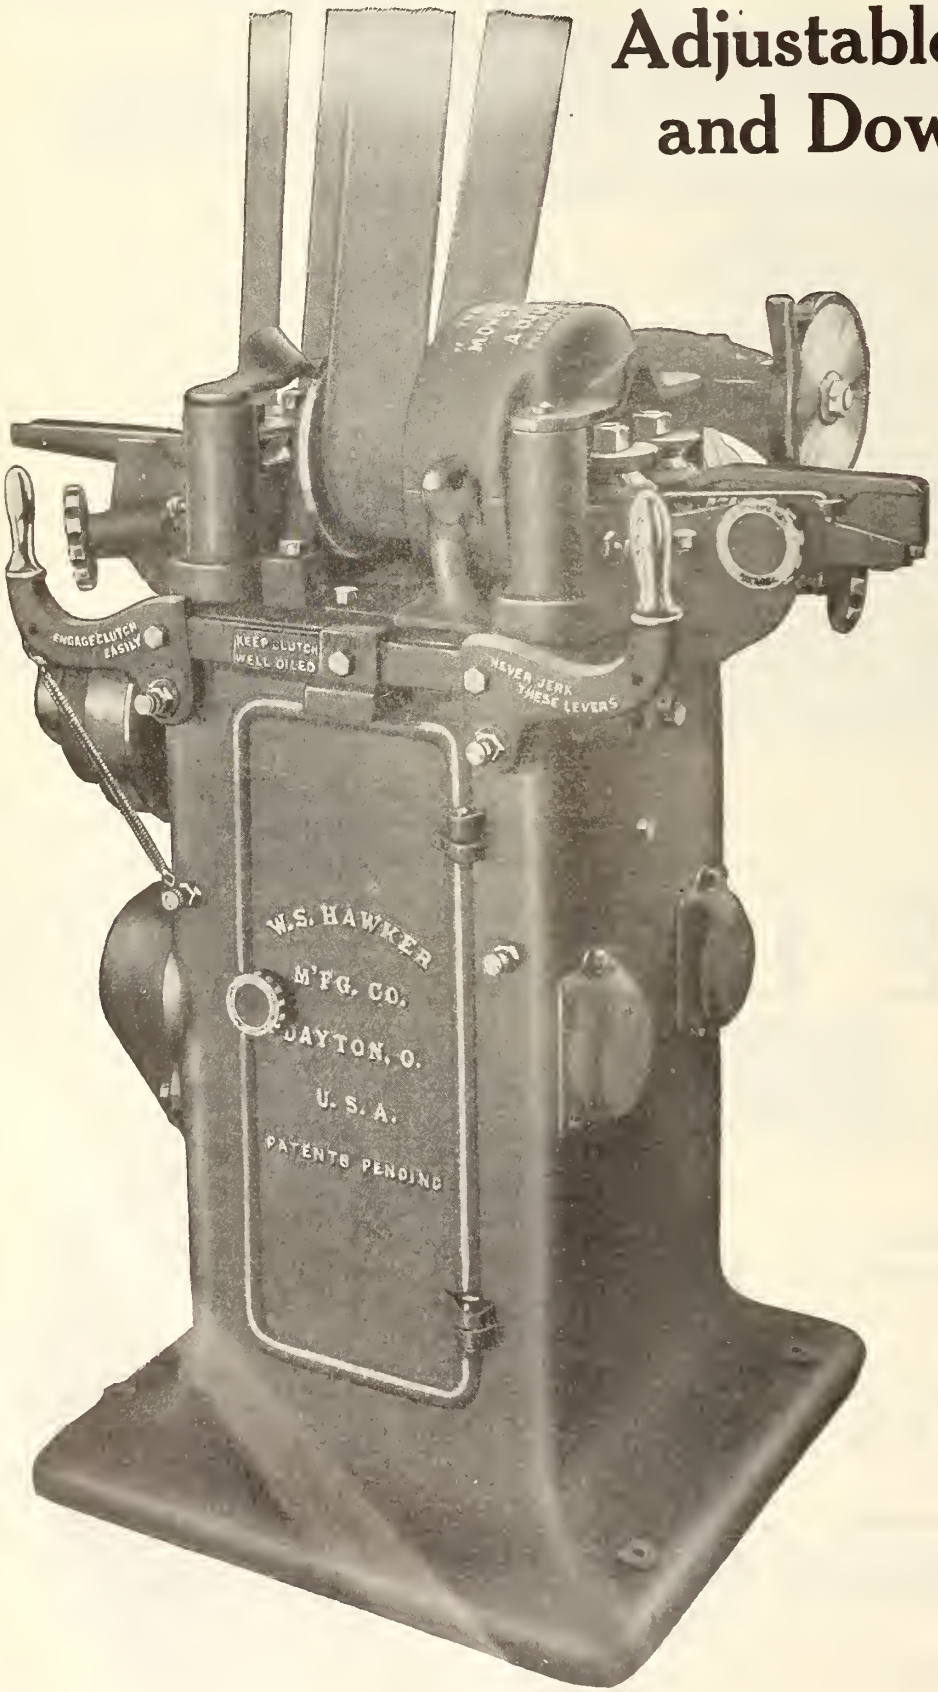
The Money Maker—
Adjustable Rod and Dowel Machine

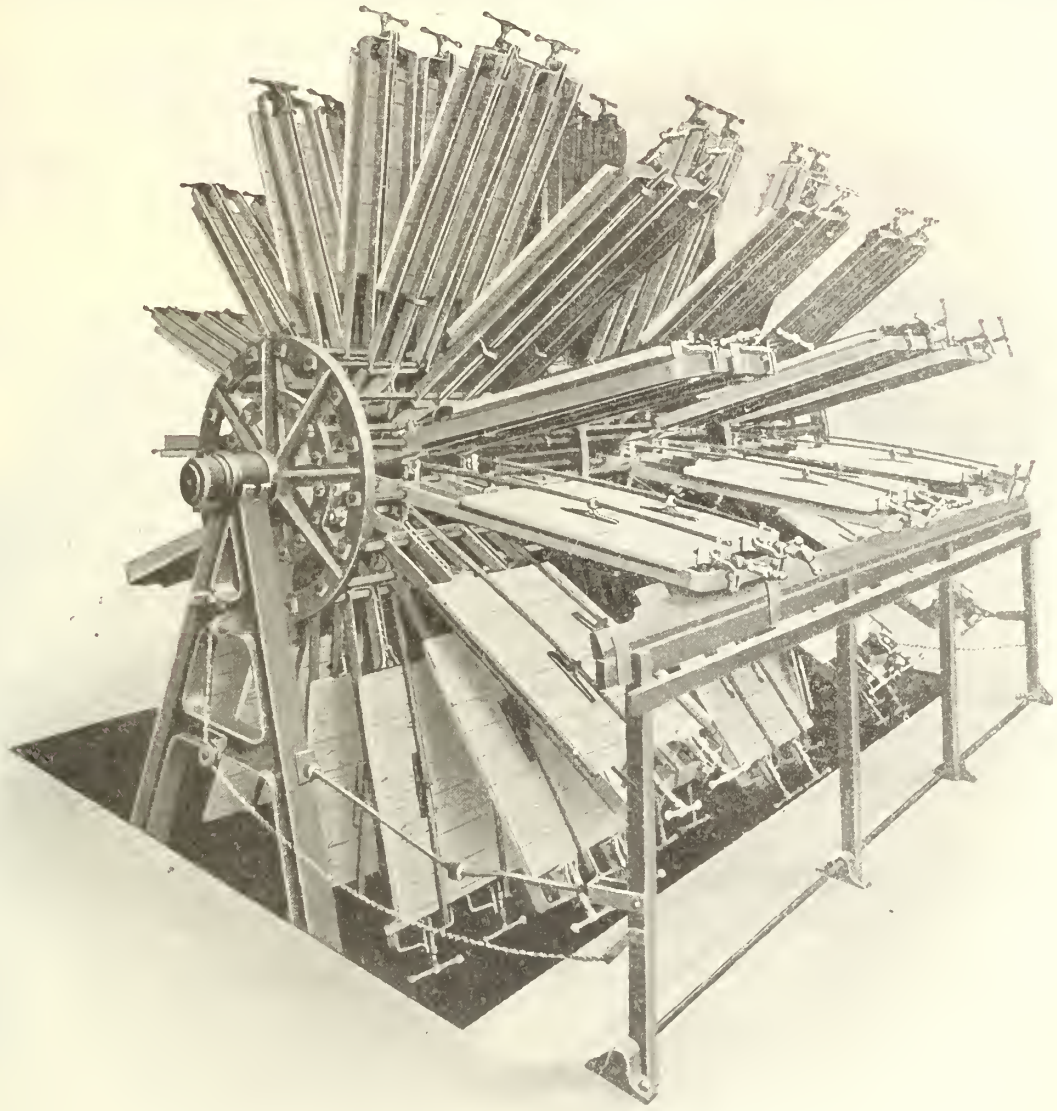


Capacity 30,000 to 40,000 lineal ft. per ten hours on 7/8 or 15/16 mop or sweeper handle stock.
If you are using any dowel machine of less capacity, figure your daily losses in labor and business.
Write us what dowel sizes you turn, and whether hard or soft wood. Ask for our demonstration proposition to show you how to double your production of dowel stock at the same labor cost.

The machine that is sent under a guarantee to show you a gain of from 100 to 400 per cent before you buy it.
The improved dowel machine that 90 per cent of the largest and oldest machinery builders and dealers now endorse and recommend in preference to the solid chuck machines they themselves previously built.
One cutter head turns from ¼-in. to 2-in. diameter.
Turns hard or soft wood equally well.
Handles heavy, oversized squares.
No choking of the cutter head.
Smooth stock.
Accurate sizes.
Works stock as short as five inches.
Rolls automatically center variations in squares.
Machines built to turn from ⅛ to 6-in.
We want to hear from every user of a solid chuck dowel machine.
We can save you from one dollar out of every two, to four out of every five that the operation of solid chuck machines costs you.
Engagements for competitive test solicited.
Formal orders not solicited. All sales made after demonstration.

The only question is, are you willing to cut cost of your dowel turning to one-half or one-third of what it costs with any make of solid chuck machine?
Machine delivers the goods before you buy.
State conditions of stock closely
Special conditions require special equipment.

W. S. Hawker Mfg. Company, Dayton, Ohio



For Cores and Solid Work

This machine is scientifically designed and constructed to insure the greatest efficiency together with simplicity of operation.

It insures the rapid making of good glue joints and holds the stock off the floor until the glue has set.

With this clamp one man can produce more and better work than two can produce under old methods.

It will prove a wonderful investment for any plant where a quantity of edge gluing is done.

It is made in sizes to suit customers requirements.

Each clamp is equipped with side brackets for short stock and a spring steel binder for thin stock.

Unequalled for clamping chair seats, furniture, dimension stock, school desks, panels, tops, etc.

Descriptive circulars and information gladly furnished on request.

Cheap Workmanship Is False Economy

You cannot afford to take chances in the installation of a

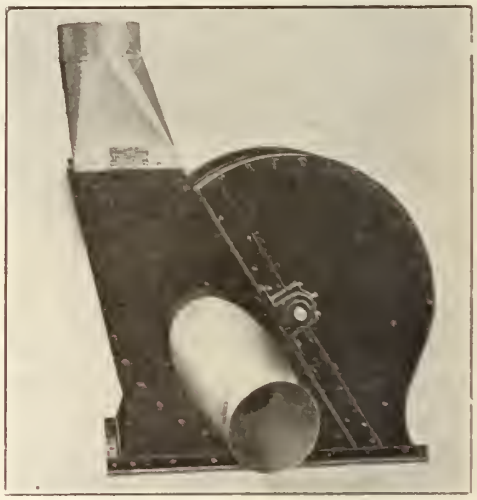
BLOWER SYSTEM

Expert workmanship spells real economy in the installation of blower systems, for it eliminates the unnecessary breakdowns and replacements that make the upkeep of a cheap system expensive.

A Toronto Blower System in your plant ensures the utmost in efficiency, for our systems are the result of long experience and exhaustive study into every requirement. One of our experts will gladly consult with you and furnish estimates.

The Toronto Blower Company
156 Duke St. Toronto

"Free your factory with a Foster Fan"



THE FOSTER FAN

The Foster Fan is the only non-centre suction fan in existence and is designed and constructed to furnish the maximum lifting power at the minimum expense. It is practically indestructible and handles all materials, wet or dry, without clogging. Installed complete. No part of installation is re-let.

IMPERIAL Tables Are Made From Stock Cured in

The GRAND RAPIDS VAPOR KILN

IT is the verdict of established and successful firms such as Imperial Furniture Co., Kroehler Mfg. Co., Berkey & Gay, S. Karpen & Bros. and more than 1,000 other leaders in the Furniture Industry that the Grand Rapids Vapor Kiln deserves the credit for the greatest single improvement of the decade in wood curing methods.

St. Johns Table Co., Sligh Furniture Co., Wm. French & Son, Inman Furniture Co., and hundreds of other manufacturers of famous products not only know from long experience that the Grand Rapids Vapor Kiln means a better product at less expense and with more profit, but they back that knowledge with repeat orders for more and more Grand Rapids Vapor Kilns as production requires enlarged curing capacity.

Imperial Furniture Company, having replaced various other kiln equipment with 12 Grand Rapids Vapor Kilns, find that curing capacity is not only increased at less cost for drying but that waste common to other methods is entirely eliminated and curing time radically cut in spite of better results. These views illustrate yard layout, operating pit and transfer track of battery entirely designed and installed by us.

We maintain, as the very foundation of our continued leadership, America's most highly specialized and efficient laboratory service serving the woodworking industry. Technical bulletins covering practically every phase of wood curing problems are yours FREE upon request and the personal service of our corps of experts here and abroad is offered without placing you under the slightest obligation. 'Twas the Night before Christmas!

'Twas the night before Christmas,
And all thru the kiln
The warping and checking
Were bothering old Bill.
So he called up old Santa
and said, "Say friend clause,
Wont you do me a favor
And bring for the Boss
That new book on the kiln
That's so easy to run?
Not one long on 'claims,'
But a much surer one,
That dares point to users
And willingly say,
'Ask them—direct—
That's the surest way.'
Just write to The Standard,
1542 McCarty St.
The book they will send
Is valuable, complete.
If you'll do that, Friend Santa,
You'll help us all the year;
For the results will mean profits
As well as good cheer."

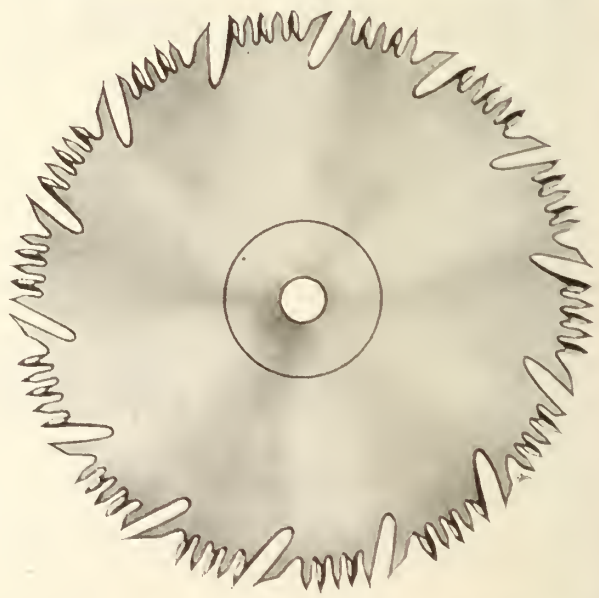
Only Cheap Saws are Expensive

Beaver Brand Saws are made to endure—to give long service and to hold their cutting edge. That is why they invariably prove economical. Were you able to follow a Beaver Brand Saw through all the stages of manufacture, from the crucible to the final inspection, you would declare without hesitation "Here is a saw that will endure."



Give your saw repairs into the hands of our experts. Be sure that name of owner appears on each saw, and mail full instructions of work to be done, stating the hand, speed and feed of mill together with shipping directions for return of saws.

Plywood door for exterior use.
Made by Rockwell Mfg. Company

Monite Waterproof Glue
endures changing extremes of moisture, heat and cold—for interior or exterior work.
Monite Sticks to Its Job

This Plywood Door for Exterior Use

Extract from a recent letter:

Milwaukee, Wis. December 19, 1921

"It is a source of satisfaction to recommend Monite Glue as entirely satisfactory for all woodwork purposes. During three years of constant use of Monite Glue no complaint of our products has been received. In addition, it saves time and labor because of the simplicity of its preparation. It covers 15-sq. ft. more of surface per pound than any other glue we have used. It has always proven dependable."

—The Rockwell Manufacturing Co.

Until Monite Waterproof Glue became available, all attempts to use plywood for outside doors, failed. They would not stand up under exposure to sun, rain, frost and snow.

The Rockwell Manufacturing Co.'s plywood doors made from selected wood of the highest quality, and glued with MONITE, are as beautiful as they are durable. They are sold, not only in every state in the Union, but throughout the world—and no condition of outdoor climate has yet been found too severe for them.

For, Monite Waterproof Glue endures all extremes of dry and wet, heat and cold. It gives the manufacturer new sales possibilities for his products—and insures satisfaction. New products in almost every woodworking line are made possible by Monite Waterproof Glue.

Get our vest-pocket sample panel of Monite-made plywood. Boil, bake, soak or steam it—MONITE STICKS TO THE JOB.

A Thirty-five Years' Unbroken Record

Of Fulfilling Sales Contracts Regardless of Market Changes

AT all times it is important that buyers of Southern Hardwoods look well into the reliability of the lumber manufacturers they deal with. It is doubly important in such times as these when the market is advancing. There are strong indications of further advances and buyers should protect themselves by placing their orders with concerns who can be relied upon to execute and fill their orders in an advancing market; who can also furnish stock fully up to grade under any conditions.

The Chapman & Dewey Lumber Company has the reputation of never having failed to fulfill a sales contract regardless of the market. This is an unbroken record extending over 35 years.

AMERICAN WALNUT

Advertisements

To swell the swiftly rising tide of walnut popularity

The demand for American Walnut for all purposes — furniture, interior woodwork, phonographs, fixtures, panels, radio cabinets, automobile trim, store interiors and show windows — is the unanswerable argument proving the overwhelming and growing preference of the public in its favor today.

To make the market still greater this comprehensive list of national magazines and business publications will carry the story of American Walnut during the period ending December 31, 1923. Consider what this means to you. How each of these millions of advertisements is an active sales builder for walnut you have to sell. Are you fully prepared to take care of this demand?

Samples of American Walnut consumer literature mailed free to you upon request

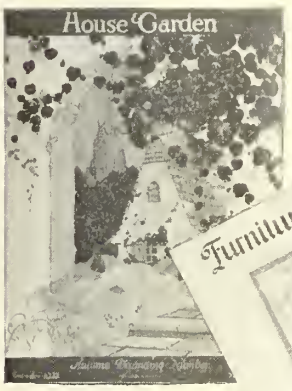
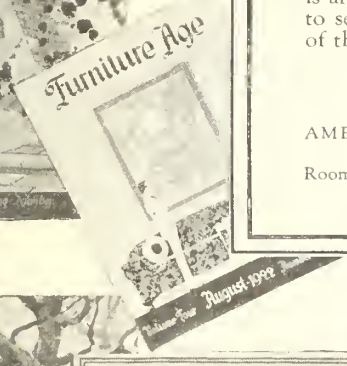
GOOD FURNITURE *Magazine*





THE ARCHITECTURAL FORUM

OCTOBER
1922

"Better Use Birch"

The Beauty of Birch

Typically Canadian in its beauty is Birch, and compares well with the rare woods of tropical lands. Captive sunlight gleams softly in its natural coloring and adds an elusive charm to this marvelously figured wood.

The light natural shade without great variations, permits of a vast range of stains being used. The velvet surface then becomes satin for Birch is close knit and takes all finishes well.

Little wonder that the furniture manufacturer is turning to Birch, for with its great beauty it combines extreme hardness and durability. Panels of Curly Birch are particularly desirable in furniture creations.

Bedroom Suites of Birch in different finishes blend harmoniously with interior decorations and are exceptionally saleable because of their moderate price.

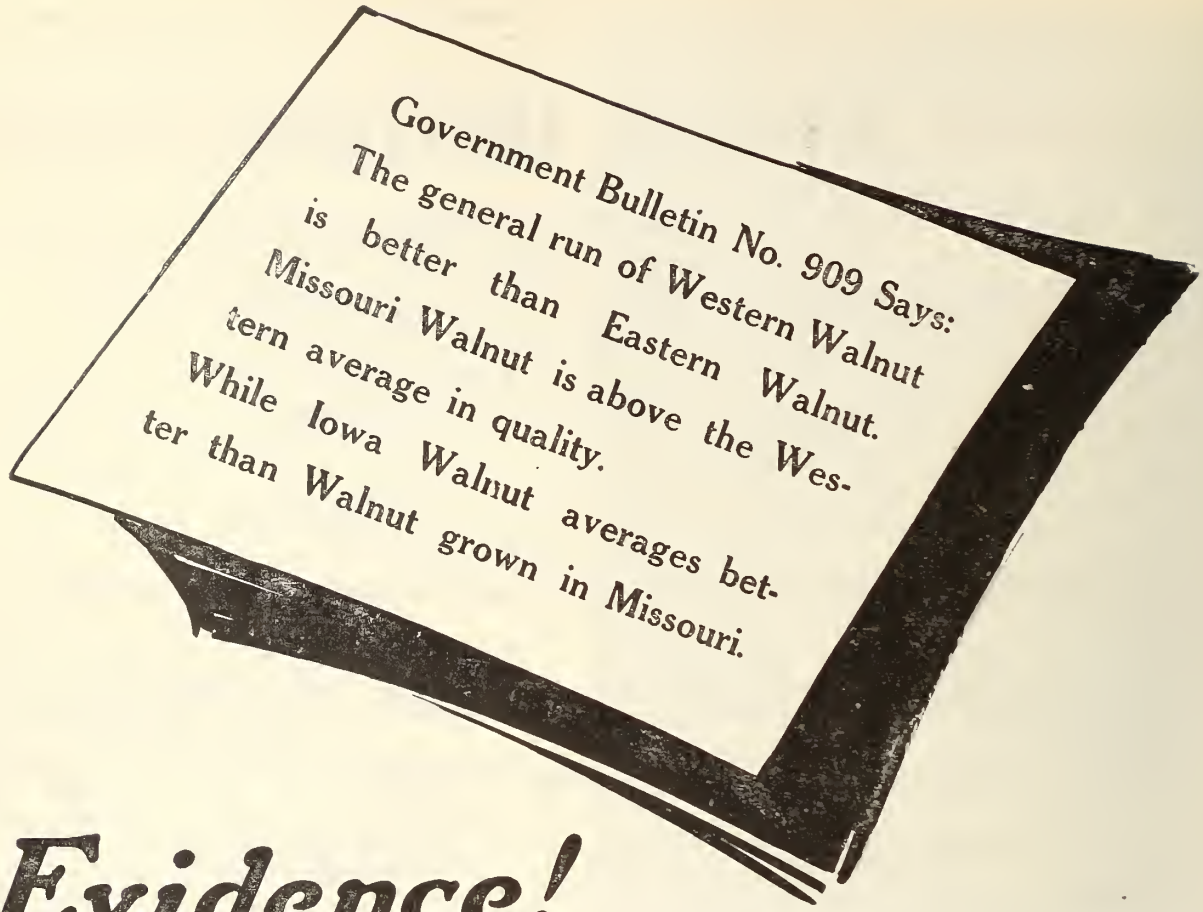
BARR-HOLADAY LUMBER CO.

BAND MILL AT LOUISE, MISS. GREENFIELD, OHIO



Government Bulletin No. 909 Says:
The general run of Western Walnut
is better than Eastern Walnut.
Missouri Walnut is above the Wes-
tern average in quality.
While Iowa Walnut averages bet-
ter than Walnut grown in Missouri.

Evidence!

During the War the government department of agriculture made a careful investigation of Walnut production in the United States. The extracts above are from this report.

Evidence, is it not, of a very convincing sort, of the quality of **Iowa Walnut**? The Iowa fields have not been cut over. The trees grow mainly in the fertile river valleys on the same soil that produces the famous Iowa Corn.

Nature has favored this product so lavishly that it is small wonder so many of America's leading furniture and cabinet makers choose Iowa Walnut for the pieces in which they take particular pride.

Write or Wire

Write or wire for prices on your needs. You'll find Iowa Walnut no higher than you pay for ordinary Walnut.

Produced by St. Lawrence Furniture Company

For Furniture of simple design you naturally select Birch

BIRCH supplies that touch of the exquisite, the colorful, that at once transforms the merely pleasing into an object of rare charm and compelling interest. We have an example of this in the piece of furniture shown above.

Pleasing as this design undoubtedly is, its real charm lies in the depth and tone of the material used in its construction. The manufacturer—who is noted for his keen sense of the selling value of materials—has rightly chosen the premier Canadian hardwood, and the result is—success.

There are many other manufacturers who could use more Birch to the same advantage. Are you one of them?

We extend to our customers and the trade in general our best wishes for a Merry Christmas and a Happy, Prosperous, and Successful New Year.

Yours for 1923

MAHOGANY

Rarely are such stores of precious wood to be found as may be seen in our yards. Across the seas from tropic lands it comes. From thick jungles where the light of day but dimly penetrates and where tangled native paths make difficult the bringing out of timber. Here the black man labors, risking life from jungle dangers, that supplies will not diminish and your orders may be filled.

Twelve million feet per year is the capacity of OTIS mills. An adequate supply is always on hand for prompt shipment. Get our prices.

THE ATLANTIC LUMBER CO., 310 Manning Chambers, Toronto

MANUFACTURERS SOUTHERN HARDWOOD LUMBER

Yards: BUFFALO, N.Y.

Mills: KNOXVILLE, TENN.; FONDE, KENTUCKY

A Permanent Lumber Service

AFTER several years of inactivity we are now cutting on our modern fully equipped mills at Manistique and Little Lake, Upper Michigan. The timber behind these mills was purchased many years ago by the Stack interests from the then "unlimited" supply. Its quality, particularly the maple and birch, is the envy of northern mill men among whom this tract is famous.

This timber will run the mills to full capacity for fifteen to twenty years. The 40,000,000 feet annual cut will run:

15,000,000 ft. maple annually
6,000,000 ft. birch annually
2,500,000 ft. beech annually
2,500,000 ft. elm annually
900,000 ft. basswood annually
200,000 ft. ash annually
3,000,000 ft. white pine annually

the balace in Spruce and Tamarack.

Our exceptional service, grades, and manufacture will be maintained. "Low freight rate shipments by water to Toronto, Montreal, Owen Sound, Port Arthur, and other Great Lakes and St. Lawrence River Ports. Conveniently located also for rail shipments to inland points by the C.P.R. or Soo line."

We will be pleased to hear from old friends and from new ones who can understand and appreciate what permanent connection with such a source of supply would mean.

Dependable Shippers of American Hardwoods

ESTABLISHED 1892 INCORPORATED 1916

ROBT. BURY & CO., Canada

LIMITED

1 Spadina Avenue, Toronto

Our Dry Kilns have a capacity for drying 200,000 feet per month. We will dry your transit cars

All Canadian and American Hardwoods
Mahogany, Walnut, Veneers and Panels of every description

Kiln dried stock carried in all woods

VENEERS—Mahogany, Walnut, Oak, Birch, Basswood, Ash, Maple, Elm and Gum
Log run or cut to dimension

PANELS—Birch, Basswood, Ash, Maple, Elm, Mahogany, Walnut and Oak

We Specialize in Mixed Shipments of Dry Hardwoods, Veneers and Panels

This is a good time to conserve your capital by making purchases in this manner

Head Office and Veneer Warehouse

The Deciding Factor

The question of the wages paid in the woodworking industry is usually a fruitful source of discussion whenever the subject is mentoined. Those who have given the matter more than a passing thought and who have taken the trouble to compare the rates paid with those prevailing in other fields are usually quite willing to admit that woodworking wages do not compare at all favorably. That is about as far as they are able to go, for with the low level of values established for wood products and with the keen and at all times unenlightened competition which prevails, it is extremely difficult to see how higher wages could be paid without ruining a vast majority of the woodworking establishments. It seems to be a kind of an impasse where the employers in the woodworking industry would like to give their men more money but can't.

In view of this, the suggestion that it is not what is paid but what is produced that counts may open up a new line of thought. At a very low rate of production twenty cents an hour might be away too much, while for the same class of work and under identical conditions but with a much higher rate of production, one dollar an hour might be too low and a higher rate could well be paid. This would seem to place a different aspect on this question of wages and might even be said to contain a hint that to a certain extent the employers themselves may not be entirely free from responsibility for present wage levels in their industry. However, most of the blame, if blame there be, must rest on the shoulders of the executives for to a large extent the productiveness of the plant as a unit, and of each individual operation, depends on the way the plant is equipped and organized and upon the spirit of co-operation which has been engendered between employers and men.

There is a limit to what can be produced so there must be a limit to what can be paid, but has the limit of productiveness been reached in the average woodworking plant. It is said, based upon results secured in many plants, that a method of paying for what is produced at rates that are accurate and which bear a relation to maximum output, usually results in a marked increase in output. When the rates or standards are developed in an intelligent manner and upon an accurate permanent basis, such a method is extremely fair to all concerned.

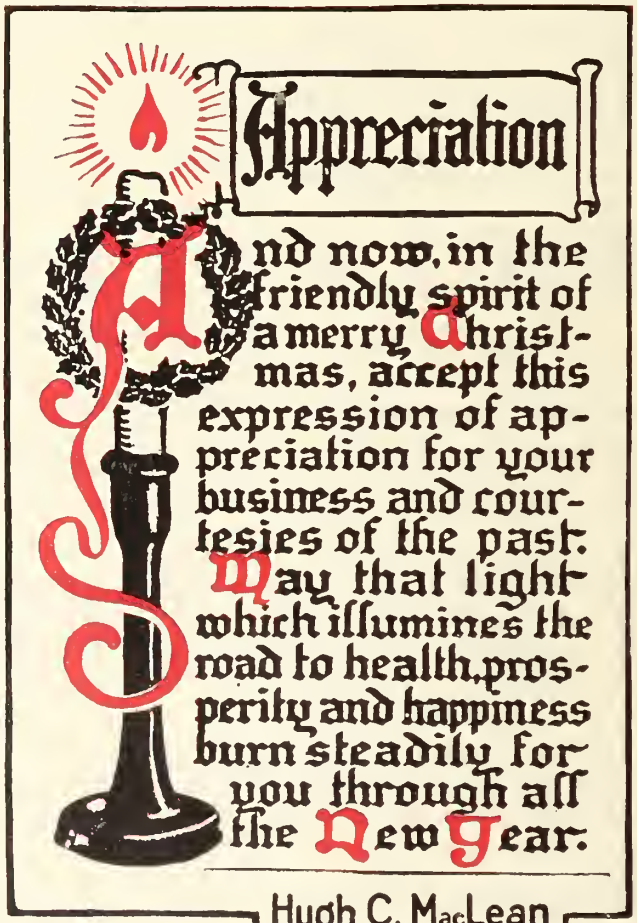
Elsewhere in this issue are given a few illustrations of what has been achieved in several plants in the direction of increased output. These would seem to indicate that there is plenty of scope for improving the productiveness of the average woodworking factory. With such increases in output and corresponding decreases in costs possible, there would seem to be no logical reason why proper planning and proper co-operation, a wage much better than that which is paid at present should prevail. In one of the instances to which reference is made, a workman increased his earnings forty-eight per cent. This in itself would seem to indicate what can be accomplished through an incentive plan developed on a proper basis.

Looking at the question of wage levels and productiveness in this light, it would appear as if everyone from the manager down to the humblest employee should be interested in increasing the ratio of production and thus making higher earnings possible. Yet, often, when an attempt is made to apply a plan of this kind, the very employees who stand to gain are the ones who resist and condemn such an installation. While a number of reasons might be assigned for this attitude, nevertheless it is a very short-sighted one, for regardless of how they are paid, their earnings must bear some relation to what they produce, only under an incentive plan they benefit directly in proportion to the extra effort put forth

This idea should provide food for thought on the part of both employer and employee. If opportunities for materially increasing production exist in every woodworking plant, and there is no doubt but that they do, all concerned are vitally interested in leaving no stone unturned to secure maximum output from each operation for all stand to benefit.

Saying you can do a thing isn't self-confidence—it's knowing you can do it.

Business is like a wheelbarrow—it stands still unless someone pushes it.



Appreciation
And now, in the friendly spirit of a merry christmas, accept this expression of appreciation for your business and courtesies of the past. May that light which illumines the road to health, prosperity and happiness burn steadily for you through all the New Year.

Reducing Costs in Crate Construction

The Firm That Makes a Study of its Packing Requirements will be Able to Effect Important Economies in its Shipping Department—Properly Designed Crates Correctly Constructed from the Right Kind of Lumber will Save Money

By Albert W. Luhrs*

It is obvious to any one making even a cursory examination that in many furniture plants the method of packing and crating shipments have, like Topsy, just growed. In many instances the foreman in charge of the packing room has held the same position for so many years that he believes there is nothing more for him to learn about crating, and all too many plant superintendents are in accord with him. Consequently, even though improvements are continually being made in woodworking methods, in the handling of material, and in practically all other departments of the plant, nevertheless the crating continues the same as it has been for many years. With what result, do you ask? Why, with the result that factories with carefully studied systems of packing and crating based on research, tests and engineering principles are producing a container for their shipments that is frequently much lighter and less costly than the packing used by many of their competitors for the same article. Yet that is not all, because another important benefit of such a study is the fact that the shipments, if shipped in properly designed containers, usually reach the consignee in good condition. This of course, means more prompt payment of invoices, greater turnover for the retailer with a consequent increase in the manufacturer's output, and the good will of the trade—one of the manufacturer's most valued possessions and which all are striving to obtain.

Fig. 1—A typical crate made from waste lumber

Crating Lumber

Let us discuss the question of costs; first, in connection with crating lumber. On this point different plants have radically different ideas which run from the one extreme of buying crating lumber cut to size S2S, to the other extreme of buying what practically amounts to saw-mill refuse, knotty, waney, barky lumber, or rotted, tongue-and-groove, reject flooring. As a general rule, furniture shippers of either class are losing money, the only possible exception being where a plant produces large quantities of one product and buys its crating lumber cut to size, but even in such a case it is usually advisable to use a type of container other than a wooden crate, such as, for example, a wirebound box or crate, or a veneer panel box, or a strawboard or fibreboard box, the one to be used obviously depending on the article being shipped.

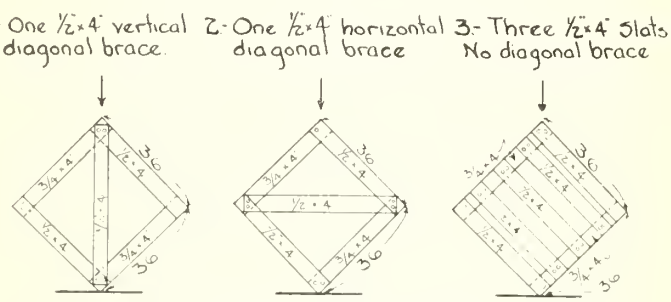

Fig. 2—Boxes with diagonal braces are stronger than those with cross slats as shown in Fig. 4

Most furniture manufacturers purchase lumber from a source some distance from their plant and as a general rule the freight charges on the lumber exceed the actual cost of the lumber. For this reason, a 30% increase in the cost of the lumber at the source will usually make not more than a 15% increase at the furniture manufacturer's plant. The 30% increase at the source is ample to cover the dif-

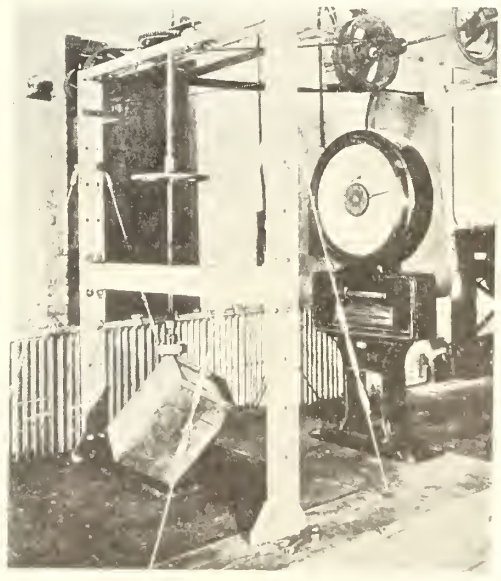

Fig. 3—A machine for the testing of boxes

*Container engineer, Freight Container Bureau, American Railway Association.

ference in cost between a poor grade of crating lumber and a good grade and the question then resolves itself into whether it is advisable and economical for the shipper to buy a good crating lumber and pay an increase of 15%, at his plant, over the cost of a poor crating lumber. The answer is usually yes, for the

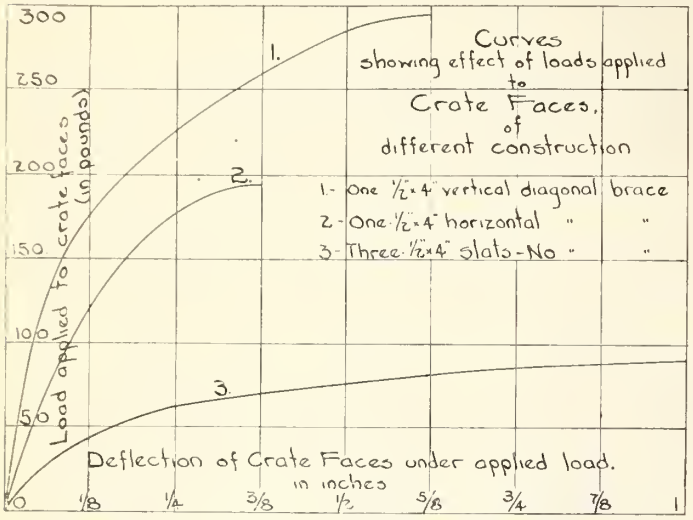

Fig. 4—This curve shows the superiority of diagonal braces

reason that more than the excess cost will generally be gained by a saving of the labor which would be required to saw out the bad defects of the cheap lumber, as well as the fact that where there will probably be a waste of less than 10% in the one case, the waste may frequently run as high as 25% to 30% in the other. In addition the indefinite saving or profit due to the difference in the condition of the furniture on arrival at the consignee is an important item and not to be overlooked.

Somewhat the same line of reasoning applies to the manufacturer who thinks his crating costs him very little because he uses the wastes of his factory. Here, his additional labor in sawing each piece of waste to the proper size and building his crates out of that lumber, almost every piece of which is either of a different width or thickness, is often very much more than what his crating costs should be. A careful examination of costs would probably convince him, as it has others, that a large saving could be effected by using his waste lumber for power generation and constructing standardized crates of lumber purchased for that purpose. Figure 1 shows a typical crate constructed by a company that uses its waste lumber for crating purposes.

Should Light or Heavy Crating Lumber be Used?

Should a heavy or light wood be used for crating? The answer to that question depends both on the difference in cost of the woods, their relative weights, and whether the shipper or consignee pays the freight either directly or indirectly. This matter is one of far greater importance than would be indicated by the little time spent on a consideration of it by most shippers. As an illustration let us assume the following:

Number of shipments per year..	30,000 pieces
Average f.b.m. per crate	18
Average cu. ft. of lumber per crate	1.5
Average freight rate	$1.00 per 100 lbs.
Cost of elm, beech, oak or ash ..	$24 per M.B.M.
Cost of spruce, fir, white pine, or western yellow pine	$32 per M.B.M.
Average weight of elm. beech. oak or ash	42 lbs. per cu. ft.
Average weight of spruce, fir, white pine, or western yellow pine	27 lbs. per cu. ft.
Assumed waste for cutting	10% in each case

Then, in the case of the hard woods, the cost of lumber per year will be:

$$\frac{30{,}000 \times (18+1.8) \times 24}{1000} = \$14{,}256.$$

The cost of freight per year on the lumber in the form of crates will be:

$$\frac{30{,}000 \times 1.5 \times 42 \times \$1.00}{100} = \$18{,}900.$$

Total cost of lumber and freight on lumber will be $33,156.

In the case of the soft woods the cost of lumber per year will be:

$$\frac{30{,}000 \times 18+1.8) \times 32}{1000} = \$19{,}008.$$

The cost of freight per year on the lumber in the form of crates will be:

$$\frac{30{,}000 \times 1.5 \times 27 \times 1.00}{100} = \$12{,}150.$$

The total cost of lumber and the freight on lumber will thus be $31,158.

Or, in the above case, a saving of approximately $2,000 in favor of the lighter woods.

It must be remembered that the above example

Fig. 5 (left)—well constructed crate containing six chairs. Considerable saving could have been made if paper bags had been used instead of excelsior.

Fig. 6 (right)—an example of bad practice. The furniture is liable to be seriously rubbed by the crate members.

is based on assumptions of conditions that vary at every plant and depend on local conditions. If, however, the problem is worked out, using your own figures you can readily determine the advisability of continuing to use the lumber you are now using or changing to a different species. The figures used above for the weights of different species of lumber are for air dried wood or, in other words, wood having a moisture content of from about 12 to 15 per cent.

The Use of Diagonal Braces

The advisability of using diagonal braces is apparent to many shippers, yet there are countless others who, because they do not understand the advantages of a diagonal as against the usual cross slat, still do not use them. A cross slat, or in other words the vertical or horizontal piece of wood nailed to two adjacent and parallel frame members, helps but little towards stiffening the crate, whereas a diagonal brace, or a strip of wood running from one corner to the opposite one, makes a remarkable difference. As an illustration of that, figure 2 shows three frames each with the same outside dimensions and each constructed exactly like the others, except that two had one ½" x 4" strip nailed diagonally across each of them while the other had three ½" x 4" strips nailed across it. These were all placed in a testing machine similar to the one shown in figure 3, and the results as shown in figure 4 were obtained. From figure 4 it can be seen that even though it required considerably fewer nails, less labor and less lumber to construct the frames with the diagonal brace than the frame with the 3 slats, they were from 2 to 3 times as strong as the other. The results obtained can be roughly verified in your own plant merely by nailing up several such frames and by pushing down on one of the corners. The great difference in strength will be readily apparent.

The results of such an experiment should teach us that, if the nature of the contents of the crate allows, many of the cross slats now used in an attempt to stiffen the crate should be done away with and a diagonal used on each face in its place, thereby allowing a considerable saving and yet obtaining a stronger crate.

Run Slats Across Shortest Span

While on the question of cross slats, it might be interesting to point out that if the cross slats were run across the shortest dimension of a face of the crate instead of the long way as is now often done, much thinner lumber might be used with exactly the same protection to the shipment. For example, where a 1" slat on a long span, say 6 feet, would deflect 1" at its center under a certain load, a slat to give the same deflection and consequently the same protection under the same load on a 2-foot span would have to be only ½" thick. The proper thickness of lumber to use for different spans can be calculated by means of the beam flexure formula and curves have been drawn, based on the results of the calculations, which show for any span what thickness of lumber will afford suitable protection to the shipment.

Paper Bags

Figure 5. shows a well constructed crate containing 6 chairs. This shipper could have made a considerable saving on this shipment however, if instead of using the excelsior pads as he has done, he had used paper bags. In this case, where the chairs are suspended in the crate at no point closer than 1" to the crate and the crate is stiffened with diagonal braces so that there is no possibility of the frame members of the crate rubbing against the furniture, of which bad practice figure 6 is an excellent example, the only protection needed is a protection against moisture, dust and dirt. For this purpose a paper bag would have served admirably, in fact, even better than the excelsior pads because of the possibility of the excelsior pads printing on the finished surfaces. And what would be the difference in cost? Here are actual figures from one chair shipper for material only:

Chairs in Excelsior Pads

33 pads	$0.341
3 lbs. newspapers	0.015
¼ lbs. tying-up twine	0.050
	$0.406

Chairs in Paper Bags

6 bags	$0.24
	$0.24

This shows a saving of 16.6 cents for each 6 chairs in packing material alone. The saving in labor

Fig. 7—A chair wrapped in paper bags

will vary greatly in each factory but it can easily be appreciated that it takes far less time to slip a paper bag over a chair than it does to tie on the excelsior pads. It is quite possible that some manufacturers have not previously heard of the use of paper bags for chairs. Briefly, a bag is usually made of a 25 lb. kraft paper, which is cut, folded and pasted together so that when opened it is of such a size as to completely cover one chair. Most chair manufacturers using bags order a few different sizes and it has been found that with those few sizes practically their entire output can be satisfactorily covered. Figure 7 shows a chair covered with such a bag.

Lock or 3-Way Corners

Many shippers are using a lock or 3 way corner but there are still others who are failing to take advantage of it. Figure 8 is a sketch showing one of the 16 ways in which such a corner can be constructed. Its advantages over any other corner lies in the fact that all the nails driven through each

piece of wood are driven into the side grain of another piece, whereas in any other corner construction having but 3 pieces meeting at the corner, some of the nails have to be driven into the end grain of another piece. As nails driven into end grain do not hold nearly as well as nails driven into side grain, the entire crate, if now constructed without lock-corners, can be greatly strengthened by the use of a lock-corner at no increase in cost.

Use of Cement Coated Nails

Figure 9, which practically speaks for itself, shows the results of tests made on the holding power of cement coated, smooth and barbed nails. I need only add that a cement coated nail holds from 20 to 60 per cent. more than a smooth or barbed nail and that its costs 15 per cent. less.

Possible Saving in Labor

As a general rule, crates are not constructed in an efficient manner insofar as the productivity of labor is concerned. In many factories the crating lumber is piled in the shipping room, not even cut to size. The articles to be crated are then set out on the floor and while one man cuts the lumber to size and another distributes the pieces, several other men each start work at one article and stay there until it is completely crated after which they truck it to the warehouse or platform and then start on another crate. At other plants the lumber is cut to size and several of the pieces are nailed together on a table. These are then distributed to the men, and the same procedure followed as before. At still other plants, whole ends, fronts and tops are nailed together, on a simply constructed frame for ease and speed in nailing, and the crate is then quickly set up around

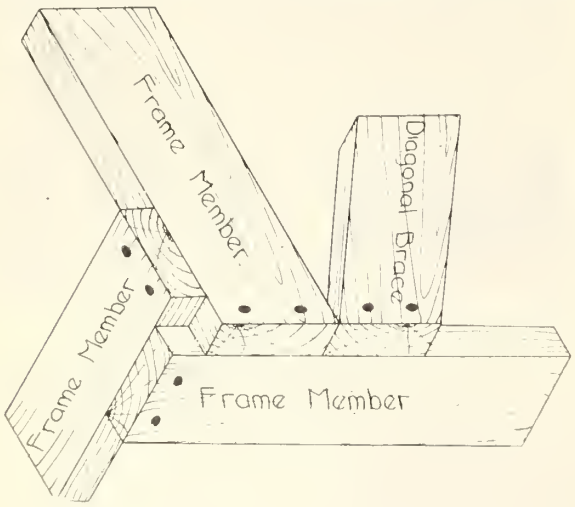

Fig. 8—Three-way crate corner with diagonal brace

the article and nailed together by several groups of men, each of which continually performs the same operation.

In the construction of crates as with almost any other article produced, efficient methods of manufacture should be used. Just what system should be employed at each plant depends wholly on conditions which will vary at different plants, and for that reason, no set of rules can be laid down that will apply equally well at all places.

It might be interesting to point out in this connection that on an investigation of a group of manufactures, each of whom manufactured and crated a very similar product the cost of labor for constructing the crates varied from 14 cents to 43 cents depending entirely on the method of manufacture of the crate, all other conditions being otherwise almost exactly the same.

The Value of a Study of the Crating Department

Because of the possible saving of money in labor and material and the considerable reduction of

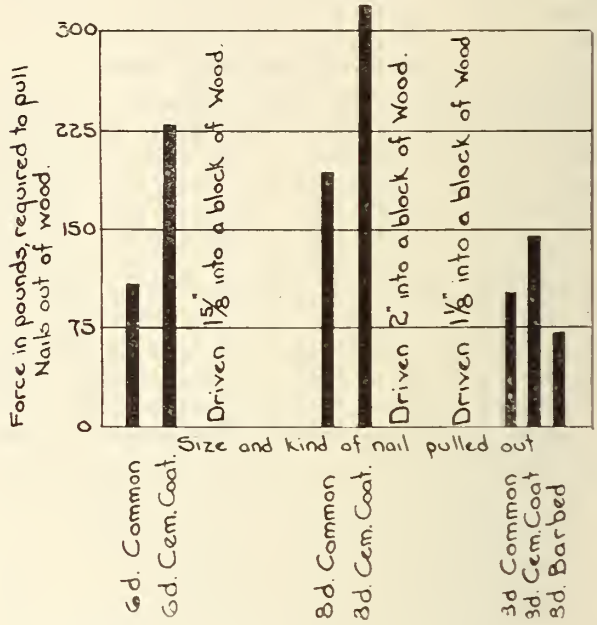

Fig. 9—Relation between holding power of common, barbed and cement coated nails

damages to shipments that may be effected along the lines brought out in this rather brief and incomplete article on the subject, it is the writer's opinion that it would be worth while for the managers of those plants who are not quite sure that their crating and shipping costs are as low as possible to either conduct, or have conducted for them by a competent engineer, a complete study of their packing activities.

The Death of Wm. Cowan

Many friends in the trade will learn with regret of the death which occurred on December 3 of Wm. Cowan, president of Cowan & Co., Galt, Ont., widely-known manufacturers of woodworking machinery. The late Mr. Cowan was in his 82nd year and although he was at his desk in his office until three weeks before his death, he had been in poor health for several months. His passing removes one of the foremost men in the industry and the organization which he directed for the past thirty years has contributed much towards the advancement of the woodworking industry in Canada. Mr. Cowan was originally a veterinary surgeon, being one of the deans of this profession in Canada. He practiced in Galt until 1881 and then became Dominion live stock inspector. His activities with the firm of Cowan & Company commenced in 1891, when he succeeded his brother as head of the company. He was always prominently connected with the affairs of the city in which he lived.

Storage economy is exceptionally important, not only in producing efficiency in the manufacturing department, but in handling raw materials and the finished products in warehouses and stock rooms.

Saving $9.19 a Day on a $4.00 Man

How Productiveness of Woodworking Plants Can be Materially Increased by Proper Organization and the Application of Practical Efficiency Principles —Costs Reduced Without Radical Change in Plant

By W. R. L.

How productive are present day woodworking methods? One often hears suggestions to the effect that productiveness of the various operations as performed in most woodworking plants is not more than half what it should be. In other words, the wood-using industry averages about fifty per cent efficient. Just why this thought should find expression is not quite clear, for the average owner of a woodworking plant feels secure in his belief that the output of his factory is just about all that could be expected. The other fellow may be falling down when it comes to productiveness and lower costs, but, he is not.

Several things have come to my attention recently which have me wonder if there is not more truth in the above thought than even the most progressive woodworker would admit. It is undoubtedly true that the woodworking industry has not been developed and advanced as rapidly as other industries which might be mentioned. This, in itself, would lead one to the conclusion that there is plenty of scope for improvement with regard to woodworking practice and equipment. And there is, but that does not touch the point I have in mind. If there is anything in the suggestion outlined it means that without making any radical changes in equipment, layout or methods the productiveness of nearly all plants, and this includes yours, can be materially increased, through proper organization and the application of practical common sense ideas, as advocated by industrial engineering organizations versed in woodworking practice.

How Production Was Increased

One enlightening incident I have in mind, and in fact the one that inspired the heading of this article, is a report I came across recently. This was issued by the Forest Products Engineering Co., of Chicago, covering an assembling operation in the plant of a client. The figures presented show, due to increased productiveness and decreased overhead per cabinet, a saving of at least $9.19 a day was effected on a man who earned a daily wage of but $4.00. Assembling 22 cabinets instead of 9 as formerly represents an increase in output of 144 per cent a figure considerably in excess of the fifty per cent suggested. However, this to me is not the most interesting feature of this report, rather it is that this saving may be laid to the door of the plan of basic time standards developed by the organization mentioned and which indicated the correct assembling time for that cabinet. As I see it, assembling times varying from 64 to 108 minutes, have prevailed for years and ordinarily the observed time of 58 minutes would have been accepted as the minimum and as a satisfactory reduction from past performance. Knowing definitely that even 58 minutes was too high and knowing how the minimum standard time of 40 minutes was obtained, it remained but to bring the time down to as near the basic time standard as conditions in that plant

Report on Assembling China Cabinets

Equipment—Case clamp

Operation—Assembling china cabinets.

The summarized average of a number of ordinary time studies indicated that an assembly time standard of 58 minutes would be justifiable. Past performance, taken from cost records, indicated varying times from 64 to 108 minutes per cabinet. Therefore a rate of 58 minutes would be a reduction of 86% from the high time and 10% from the low time.

Basic time standards, however, indicated that, with all allowances included, the assembly time of this cabinet should be only 40 minutes. A detailed comparative analysis clearly indicated that the method of assembling, although it appeared to be very good, could be improved. The result was that a basic time standard of 40 minutes per case was established. The first lot was produced in 30 minutes unit time per case, the second lot in 28 minutes and the third lot in 27 minutes.

Results

Employer's Gain

(Hourly rate, 40 cents.)

1st. Lot

Basic time standard	40 min. per cabinet.
Actual performance	30 min. per cabinet.
Difference	10 min.=33-1/3% in'se pay

2nd Lot

Basic time standard	40 min. per cabinet.
Actual performance	28 min. per cabinet.
Difference	12 min. =43% increase pay

3rd Lot

Basic time standard	40 min. per cabinet.
Actual performance	27 min. per cabinet.
Difference	13 min. =48% increase pay

Employee's Gain

Lowest previous time 64 min. per cabinet
Basic time standard 40 min. per cabinet
Difference 24 min. or 38%

Lowest previous unit cost 64 min. at 40 cents per hour=	$.43
Basic time standard cost 40 min. at 40 cents per hour=	.266
Difference	.164

or 39% reduction in cost

Overhead and all burden including executives and other salaries conservatively taken as 100%. Therefore.

Overhead per cabinet	.43
Actual production on basic time standard	22 Cabinets per day.
Best previous production	9 cabinets per day.
Difference	13 cabinets per day.
Unit burden	.43 x 13=$5.59
Reduction in assembling cost	16.4 x 22= 3.60
Estimated unit profit	??? x 13= ??
Total gain	$9.19

per day plus profit on assembling the 13 additional cabinets.

(Showing how production was increased from nine to twenty-two cabinets a day).

permitted. That this time was done is indicated by the report.

Another instance which illustrates the possibilities which are to be found in every plant for effecting cost reduction is that of a furniture factory which ordinarily employed thirty five men in its assembling department. Incentive rates were developed, based on conditions in the plant and upon basic time standards. The resultant increase in productiveness was such that eleven men were transferred from this to other departments and the total output of the department was twenty-five per cent higher than formerly or a total increase of 83% per man. Again in excess of the suggested fifty per cent.

Are Your Costs Low Enough

An eastern furniture manufacturer is saving $20,000 a year in overhead and labor costs on one item of his line. Still another—but why go on. Numerous other illustrations could be given but I think I have outlined sufficient to carry my point. What has been accomplished in certain plants can certainly be repeated in others. There is nothing illogical or unreasonable about such a suggestion. That being the case, how do your production costs line up? Are they about the same as others you know or are they so far below the average that you can undersell your competitor and still make a satisfactory profit.

It does not do much good to meditate on the past and to calculate how much could have been made or saved if ten years ago you could have brought your cost into line with what the above illustrations indicate they should have been. We are more concerned with the present and the immediate future. With such reductions in the average woodworking operation times or cost possible, are you going to be content to let things slide along in the same old groove or are you going to try and reduce your labor costs and make all the money you can?

Do You Know How to Take Off Quantities?

Quantity Surveying is as Important a Subject to the Millwork Man as Costs—Lack of Knowledge on the Matter is Causing Firms to Lose Money Unnecessarily

By H. T. Didesch*

All of you have listened to, and read so much on the subject of "Cost" that is would seem the subject had been utterly exhausted. There is, however, another pregnant subject—one so closely allied with cost as to be virtually a part of it, and one which, unlike cost, has not been expounded in any standard writings and is therefore all the more worthy of deliberate consideration. That subject is "Quantity Survey."

The surveying of millwork quantities from architects' plans and specifications is a matter that has been just as much misunderstood or ignored as has the subject of cost. Of course, the quite general failure of architects to detail fully or specify clearly just what is wanted does not contribute anything to a better performance of the quantity survey. That particular trouble, however, is your own fault, and it will continue to exist just as long as you tolerate it. Now, it may be questioned whether all men are born equal, but there is no denying that all humanity—even millmen and their estimators—is possessed of an intellect which will discover practical methods of overcoming the architects' shortcomings in respect to vagueness and the like. How?

Refuse to Figure When There is No Information

In aggravated instances, refuse to figure the job until specific information is forthcoming. Where the lack of information does not involve a major portion of the job, figure what is apparently appropriate to the character of building under consideration, and state the condition of your proposal, that if subsequent details of information should involve a more elaborate construction than that figured, an excess charge will apply, or, if it is so merited, a proper credit will be allowed. The form of proposal, therefore, is most important, but consideration of it will be deferred until later.

Our industry is slowly but surely emerging from a status of apathy, but if the progress is to continue, there must, for one thing, be just as intensive a study of quality survey and the related proposal and contract, as there is of cost, because what does it avail us to know and apply costs until we're "blue in the face," if, in doing so our estimators misinterpret plans and specifications, leave out an opening here, a course of moulding there, and, what is worse and happens right along, omit a whole floor,

Mr. H. T. Didesch

or through the employment of a doubling-up process, in their hurry to get on the next job, forget to double up and omit entirely a wing of the building. It is indeed a sad thought, but all those things, and then some, are every-day occurrences.

What is Involved in Millwork?

What are you in business for? Not for your

*Technical director, MillworkCost Bureau. This article is based on an address delivered at the annual convention of the Southern Sash, Door and Millwork Manufacturers' Association.

health; otherwise you would indulge in something more delectable than the millwork business. You are trying to make money; perhaps you aspire to great wealth. That money must be made legitimately as manufacturers. Getting sufficient jobs is you first consideration, and that entails competition. Our statutes say, "unrestricted competition;" probably you call it "cut-throat competition." Sometimes it is just that, and entirely deliberate, but, more often, it is nothing of the sort. You produce millwork. What is millwork? I have consulted four recent editions of unabridged dictionary and the Encyclopedia Britannica. So far as our product is concerned, I might just as well have consulted the Koran. Now, if the world's most eminent lexicographers fail to define millwork, how can you expect a contractor, an architect, or a plain man to agree with you as to what constitutes millwork. You do not agree as to its meaning among yourselves to; yet some of you do not hesitate in the least to dictate to your stenographers a letter to a prospective customer: "We agree to furnish the millwork for the John Robinson residence in accordance with plans and specifications prepared by Kenneth & Jordan, architects, for the sum of $5,600.00, f.o.b. Atlanta, Ga." That sort of quotation makes it incumbent upon the seller to furnish everything that the purchaser might demand as millwork. If the purchaser has dealt with a mill whose custom it was to include weights and cords, rough bucks, etc., then he will expect them in this case—whether they were figured or not—and nine times out of ten the will get them, either without any extra charge or on a part charge basis.

Other mills add to the quotation just cited, "as per itemized list attached." On the surface, that form has the aspects of safety, but it is hardly fair to the purchaser, for if he wanted to be certain that the estimate included all millwork, it would be necessary for him to check each quantity from the plans. This particular form of quotation is so manifestly safe to the seller, that most buyers will not buy on that basis. Some buyers refuse to consider such a quotation at all; many will call on the millman and among other things remark: "Your price is all right, but I want to buy this job complete and I am not sure that everything is included in your estimate." The millman expounds a bit over the accuracy of his estimator's list of quantities and finally, to thoroughly convince the buyer of his confidence, writes us an order as follows: "Millwork complete," or simply, "Millwork' John Robinson residence, $5,-600.00." The customer inscribes, "Accepted, Louis R. Carperten." Nothing further, except, of course, certain conventional printing.

A Uniform Agreement

That can hardly be termed "good business" or "legitimate competition." Nothing whatever is said about terms of payment or deliveries; the extent of work is not defined; in fact, the transaction hardly measures up to the standard of simple, economical practice. To demonstrate the point, let me read a letter from one of your members to Secretary Harman, dated September 19, 1922:

"Will you please advise us if you have in your office a form of estimate in which terms of payment are shown and which indicates how, if customers do not live up to agreement as to payment of account and otherwise, the balance of the estimate can be cancelled and action taken against customer immediately for amount due.

"We have at the present time a case in our office of a customer owing a considerable amount of money, who has not lived up to his agreement in the way of payments, yet upon our refusal to continue deliveries on the estimate in question, we are placed upon notice that unless we do so, they will buy in open market for our account. We find that under the law they can compel us to do this, and if you have a form of contract covering cases of this kind, we wish you would send us a copy.

"We think that this matter is a very important one of the members of the Association, and if some such a form does not now exist, we think that the Association should take the matter up and draw up some form under which all the members will submit their estimates."

Is there any logical reason why you should allow that condition to persist? Certainly not. Should we stand idly by and permit, nay, actually force our buyers, either collectively or individually, as they are doing, to devise protective contracts—protective principally to themselves—which they demand that we sign, when **we sell them millwork** Again, the answer is an emphatic "NO." Moreover, the remedy is so self-evident and effective, that it seems amazing that it has not been generally applied heretofore. Admittedly, you need a uniform contract or agreement. Such a contract form is printed herewith in full. I might explain that this form of agreement is not a Bureau compilation, but that is was prepared some ten years ago by a northern member, under the direction of counsel. It is a fair and just contract which explains why it has remained in use for ten years.

A Modified Blanket Bid

The memorandum list referred to in Article I, under "Extent of Work," is, in effect, a modified blanket bid; that is, it enumerates, under the title, "This estimate includes," the general classifications of material that in the bidder's eyes constitutes the millwork. Those items that might not be considered millwork, or those that for one reason or another the bidder does not wish to furnish, are enumerated also, under the title "This estimate does not include." The following is an example of such a modified blanket bid:

This estimate includes: All exterior door, window, and sash frames, set up, with pulleys placed; all windows, sash, and transoms, open; all weights and cord for check rail windows; all panel and sash doors, open; all interior frames KD and machined; all interior standing trim KD cut to approximate length; all base, picture mould, wainscot cap; 1 colonnade, columns not attached; 1 buffet, set up; 1 set pantry cases, set up; 1 mantel, set up; 1 seat, set up; 2 closet cases, set up; 1 medicine case, set up; 1 flight stairs, 1st to 2nd floor fitted & KD; all outside moulds, except as noted below; all verge boards; all rafter ends; all gable brackets, set up; all porch posts for front porch only; all rear porch rail and balusters; 1 rear porch newel.

This estimate does not include: Coal chute; priming, painting, nor finishing; interior finish for basement; thresholds nor closet shelving; glass; hardware, except pulleys and weights; rough stair carriages nor platform flooring; basement stairs; rabbeted, square edge, nor bevel edge moulds for ex-

terior cornices and beams; matched and beaded material for exterior; outside steps; rear porch posts.

In making the quotation, the memorandum is, of course, accompanied by a proper letter stating the price, terms, etc., and the phrase "as per memorandum list attached."

Permit me to point out that this form of quotation and the subsequent agreement define what is millwork. Moreover, the definition fits each particular job, which is important. The Southern Sash, Door & Millwork Manufacturers' Association some time ago adopted, and had printed, a combination uniform bid and contract form. Its psychological effect on the prospective purchaser condemns it, for, in order to be applicable to all jobs, it must list all items that are, or might be, considered millwork. Such items as do not occur on a given job are stricken through, and what remains is then the millwork included in the quotation.

UNIFORM CONTRACT FORM 1915 3M-9-15

Millwork Agreement

MODERN MILLWORK CO

This Agreement. made.....192.... by and between MODERN MILLWORK CO (hereinafter designated the seller), a ..... corporation, of ..... and.....(hereinafter designated the Buyer), of.....

WITNESSETH; that said parties, each in consideration of the agreements herein contained to be performed by the other, agree as follows:

Article 1. The Seller will furnish to the buyer free on board cars, consigned to..... the millwork for the..... to be erected at.....in accordance with memorandum list dated..... same being attached herewith and forming a part of this agreement. Of the items enumerated as included in said list, the Seller agrees to furnish sufficient to complete the work covered by this agreement in accordance with plans and specifications prepared by Architect..... of.....

Extent of Work

Article 2. All communications or agreements between the parties hereto or their authorized agents, whether verbal or written, which have been heretofore had or made, contrary to the provisions of this contract are hereby withdrawn and annulled. This contract with memorandum list attached alone constitutes the agreement between the parties hereto. No future change in any portion of the work covered by this contract or any instruction or information relating thereto shall be binding upon either party unless such change, instruction or information is in writing

Previous Agreements, Future Changes.

Article 3. Unless otherwise specified, the work included in this contract is to be executed in accordance with the plans and specifications prepared by the architects and such additional drawings and explanations as may be necessary to detail and illustrate the work to be done. Such additional drawings and explanations are to be furnished to the Seller who agrees to conform to and abide by same, so far as they are consistent with the purpose and intent of and are in accord with the original plans and specifications above referred to

Drawings, Specifications, Details.

Article 4. All measurements and information in connection with such portions of the work under this contract as are necessary for its proper manufacture are to be furnished by the Buyer to the Seller The Seller will make written requests of the Buyer for such information and measurements as it deems necessary on conveniently arranged blanks for the purpose, and the Buyer agrees to furnish the necessary information and measurments as soon as same can be established or are available

Measurements and Information.

Article 5. The work and material included in this contract shall be furnished in proper sequence so that the construction of the building may be continued without delay It is agreed, however, that a reasonable length of time will be allowed the Seller, dating from the time the necessary information and measurements are received by the Seller, to manufacture and furnish the work covered by this contract. The Buyer agrees to examine and check all shipments as they are received and report promptly to the Seller any shortage or errors, so as to give the Seller the opportunity and privilege of supplying any deficiency of material or to correct any error in manufacture No labor is to be performed or material is to be furnished by the Buyer and charged to Seller under this contract without written approval from the Seller except when the Seller's further performance of this contract has been formally terminated under the provisions of Article Six. Unless otherwise specified no material is to be installed or set up in the building by the Seller

Shipments, Errors and Shortages. Installation.

Article 6. Should the Seller at any time (except under conditions hereinafter described in this article) fail to supply sufficient material of proper quality so that the construction of the building may be continued without delay and the Seller through its own negligent acts or omissions is wholly responsible for such failure, the Buyer with the written approval of the architect shall be at liberty after five days' written notice to the Seller to terminate the Seller's further performance of this contract and proceed to procure from some other source, at reasonable prices, the necessary material to complete the work covered by this contract. In such a case the Seller shall not be entitled to receive any further payment under this contract until all of said necessary material has been so procured by the Buyer, at which time, if the unpaid balance of the amount to be paid under this contract shall exceed the expense incurred by the Buyer in furnishing the work, such excess shall be paid by the Buyer to the Seller; but if such expense shall exceed such unpaid balance, the Seller shall pay the difference to the Buyer

Parties Failure In Performance of Agreements

It is further agreed, that should the buyer refuse at any time to make payments to the Seller as provided in Article Eight (except under conditions heretofore described in this Article), the Seller shall be at liberty after five (5) days' written notice to the Buyer to discontinue further shipments of material under this contract until all delinquent payments are made.

Article 7. The Seller shall not be responsible for loss, damages or delays in delivery of any materials occasioned by the transportation company, but agrees to render to the Buyer every reasonable assistance in the collection from the transportation company of any claim growing out of the above causes. The Seller shall not be responsible for any delays in the delivery of any material under this contract resulting from fires, strikes, lockouts, or any other cause beyond its reasonable control.

Loss In Transit, Strikes, Fires, Etc.

Article 8. The sum to be paid by the Buyer to the Seller for the work and material covered by this contract is.....

Contract Price. Terms. Freight Credits

The Buyer shall pay the freight charges on said material to the point to which it is to be consigned; but on presentation to the Seller of the receipted original freight bills, the Buyer shall receive credit on said purchase price for the amount of same, but such credits shall not extend to any Federal or other tax on materials, shipments, or freight bills. The moneys to be paid by the Buyer to the Seller are to be paid as follows: Shipments or deliveries will be invoiced at their approximate value and eighty-five (85) per cent of such charges are to be paid at ..... within thirty (30) days of the date of such invoices, and final payment shall be made at ..... within thirty (30) days after the completion of the work included in this contract.

Article 9. No payment made under this contract, except final payment shall be conclusive evidence of the performance of this contract and no payment shall be construed to be an acceptance of defective work or improper materials.

Article 10. The Buyer reserves the right to make such changes in, additions to, or deductions from the work or material included in this contract, occasioned by alterations or changes in the original plans and specifications. Such changes occasioning additions to or deductions from the above named purchase price shall be made at fair valuations therefor No changes or alterations in work once ent or in process of manufacture can be made except at the expense of the Buyer for loss of labor and material.

Changes In Work

Article 11. The Buyer shall, during the progress of the work, maintain insurance, or see that insurance is maintained on the same against loss or damage by fire, the policies to cover all work incorporated in the building, and all material for same in or about the premises or elsewhere in the possession or under the control of the buyer and to be made payable to the parties as their interest may appear

Insurance.

Article 12. In case the parties to this contract fail to agree in relation to any matters in dispute that are not covered by the provisions of this contract, then the matter shall be referred to a Board of Arbitrators, to consist of one person selected by each party to this contract, these two to select a third The decision of any two of this Board shall be final and binding on both parties hereto. Each party shall pay one-half of the expense of such reference Should either party fail or refuse for a period of five (5) days after written demand has been served on him for an arbitration, to appoint an arbitrator or submit the matter in controversy to arbitration, then and in that case he shall forfeit and waive his contentions in any matters under controversy

Arbitration.

The said parties for themselves, their heirs, successors, executors, administrators and assigns do hereby agree to the full performance of the covenants herein contained.

IN WITNESS WHEREOF The parties to these presents have hereunto set their hands the day and year first above written.

A contract form that is fair and just and provides for proper protection

Three Suggestions

Now then, the ordinary job does not acquire all the items printed on that proposal, with the result that, after striking through what is not figured, there seems to be more excluded than included. The effect on the prospective purchaser cannot be good. Then also, it seems preferable to divorce the acceptance from the proposal at the time of quotation. Once the customer has decided to buy from you, then I believe is the time to set forth your terms of acceptance, etc. Aside from those two objections, which are purely of a psychological nature, your present form lacks many essential provisions. It is a contract, but an inadequate one, because a contract should protect you and your buyers, which your form does not. I will suggest, therefore, that you act along the following lines:

1. Get your estimators right in respect to quantity survey. Your cost problem itself, I believe, is rather well taken care of, but there is much room for improvement in the routine of listing plans.

2. Dispense with your present form of quotation and substitute the one suggested; namely, the modi-

fied blanket bid, which is fair to you and fair to your customers.

3. Adopt a uniform contract that will assure you one hundred per cent. protection and your buyers the same measure. The tested agreement which I read takes full cognizance of fair dealing and protection, and any instrument that ignores those two essentials will not long survive.

When Expense is Saved

Does it not seem unbelievable that this great industry called "Millwork," related so intimately with the development of the human race, the medium through which is supplied the permanent furniture for Homes, should in this age be required to occupy itself with simple business fundamentals? Regardless of whether we like it or not, those are the facts and I urge you not to ignore them but to take concerted action now.

I spoke of competition. Can you visualize any competition worthy of the name that does not involve an identical list of quantities and a logical consideration of cost, which would be your actual cost based on your own experience? Perhaps, that fellow who always takes your jobs, and whom you have "cussed" and called a price-cutter, is actually a good business man who does not furnish the "millwork complete" because the meaning of that term is too variable, but "as per memorandum list attached," and when he gets a job protects himself and his buyer through the employment of a fair agreement—not the buyer's form of contract, but his own, the seller's, by the seller's prerogative. In using that kind of contract, he automatically reduces his costs because it tends to eliminate errors in construction, stimulates collections and little, if anything, need be charged to the bad debt account. So it may be that that particular "rascal" is just a few steps ahead of his accusers.

Are Step or Flush Pulleys Preferable?

Which Do Our Readers Think Are Better?—"Hemlock Bill" Asks the Question; Let's Give Him Our Experiences

Have our readers any ideas with regard to the respective merits of step and flush pulleys on woodworking machines? On this matter there has been considerable difference of opinion, some machine operators preferring the one type of loose pulley and some the other. Undoubtedly a great many of our readers have had sufficient experience with either or both to be able to venture an opinion as to which is the best type. Such opinions would be welcomed by the editor whose attention has been drawn to this matter by a letter which has come from a woodworker who signs himself "Hemlock Bill." This letter states a case for the flush type of pulley, the writer claiming that such a pulley with ball bearings will solve belt troubles and should be ideal. A live discussion on this topic may help to clear up some of the difficulties and uncertainties of loose pulley practice. Will our readers, therefore, give the editor the benefit of their experiences? The letter referred to above is as follows:—

Dear Editor:—

The loose pulley problem like the poor is always with us. Loose pulleys at the best are an abomination and an ever present cause of trouble but it is not their general cussedness upon which I wish to unburden myself this time—it is the question of steps or no steps.

My present boss is strong for loose pulleys with steps—that is, the loose pulley is made somewhat smaller than the tight pulley and with a taper flange to assist the belt when shifted to climb up on the tight pulley. The contention is that when the machine is stopped the belt being on a smaller pulley the extreme tension is relaxed with a result that bearing trouble is somewhat lessened. My experience has been that it did help some, but in so doing caused a whole lot of belt troubles.

Unless the belt shifter was set just so, the belt soon formed a habit of climbing up on the taper flange and starting the machine, sometimes with disastrous result. One thing it did do—it soon stretched on the high side so that the laces were forever breaking. Some relief can be got from turning the belt over and letting it stretch on the other side but it was soon worse than ever. A belt stretched on one side is useless for from an inch to half its width in driving efficiency.

The boss says that these remarks are true only on pulleys that have too great a step, say 1 inch, but it appears to me that a quarter inch step that he talks about would not be much good.

My contention is that the loss of power delivered and the damage to good belting more than offsets any advantage gained. It seems to me that a good ball bearing would solve most of the bearing trouble This used on a flush type pulley would also solve the belt troubles and should be ideal.

I would like if some of the other fellows would take the time to make known their experience in this matter and hope that you can see your way clear to let some of the boys air their opinions.

Yourt truly
Hemlock Bill

Westinghouse Gear Book

In order to acquaint the industrial gear user with the advantages of Micarta Gears, the Westinghouse Electric & Manufacturing Company has issued a 20 page booklet, Folder 4506, entitled "Salient Facts on Silent Gears." The booklet describes the advantages of the use of Micarta gears and pinions and gives photographs and data describing some of their applications, tables of gear data, etc., enabling the gear user to judge whether or not they are applicable to his machinery.

It would be very interesting if every man who uses the word "tension" when speaking of saws gave a definition of what he meant.

How Produce Better Work from the Moulder?

Defects and Marks on Finished Stock Generally Due to the Conditions Under Which Machines are Operating—To Get the Most Out of Planers and Moulders Look Particularly at the Cutters and the Drive

Can it truthfully be said that the cause of defects and marks on planed boards and mouldings often lies with the machines? Isn't it more reaosnable, in view of the present high development of planers and moulders, that the fault more probably lies with the conditions under which the machines are working?

At the present time, varied forms, stock patterns of casings, crown mouldings, and the like are being put through on fast-feed moulders at a rapid rate. This is made possible by hard, high-speed cutters, properly ground, set and jointed. The self-hardening cutter is also primarily, the secret of advances in fast feed rates for planers.

Development along this line has resulted in improvements to a high degree throughout the machines, with the purpose of increasing the efficiency of operators. However, in replacing many hand operators with mechanical adjustments, a better understanding of the care and adjustment of knives and working parts is required than ever before. Some men do not understand this and consider that the efficiency of these various devices will offset carelessness and inaccuracy on their part.

Cutters Must be Balanced

The idea that the small actual bulk of the thin knives is a reason for less careful use of the grinding machine has also been expressed, this idea being supported with the argument that the comparatively small amount of metal involved would not throw the thin knives out of balance because of slipshod grinding. On the contrary, the exact balance of the cutters is a matter of vital importance in the successful working of planing and moulding machines. An absolutely perfect balance is always to be preserved. Cutters should not only be of exactly the same weight and overhang, but all must be made to agree accuracy. The importance of this is clear when the high velocity at which they have to run is considered. Consequently, inequalities are enormously multipled by the centrifugal force set up, the result being transferred to the wood in the form of marks and also by the more rapid wear of the bearing due to the constant jarring.

As the high-speed cutters are unquestionably with us to remain, it is absolutely necessary for operators to understand how to keep the profiles of knives exactly matching, sharp, evenly jointed and set at the proper angle for the wood being worked.

In touching on the various other reasons for trouble caused by no fault of the machines, those who have had considerable to do with modern methods may find little that is new to them in the remarks to follow, except that a forgotten suggestion or two may help them overcome any defective condition of finished stock.

Causes of Defective Moulding

In the first place it does little good to continually correct trouble in a machine that is placed on an old, shaky floor. Vibration is the natural enemy of all machinery possessing fast revolving parts. A shaky floor will often undo the effect of a stiff bed and frame, and develop vibration. If it is necessary to install machinery under conditions that seem to invite vibration, at least stiffen the floor directly underneath the machines with a couple of timbers, which will be of some help.

Planers and moulders should never be crowded into an out-of-the-way corner, as capacity will fall off, owing to the difficulty in getting to them with stock. Plenty of working room is an aid in handling stock and more positively assures the safety of workmen.

Badly joined belts, or belts that are not running true, owing to the machine being slightly out of line with the power shaft, will cause a break or irregularity in the speed of feed rolls and cutter heads, resulting in marked stock.

To perform their work most satisfactorily the cutterheads must be driven at a specific rate of speed. If they are driven too slow, for instance, the finished product will be inferior, as the knives will be unable to do their proper share of work. When the matter of cutterhead speed is guessed at, there is no certainty that the machine is working as efficiently as it should. An economical, sure and simple way to make certain in this matter is to apply a speed indicator to the centre of each cutter-head shaft.

Irregularity in the driving or feed of machines is often caused by a line drive of insufficient power, so that as the various heavy machines go on and off the speed of the main power shaft slightly slows down and speeds up correspondingly. Motor drives will prevent this condition occurring.

Worn feed-rolls or table of machine, or feed not square or true is often caused by a majority of stock being run through the centre of the machine. Divide your work, using the sides and centre of bed as equally as possible.

Excessive Pressure Causes Marks

Excessive feed pressure on wood will mark the stock, and also likely cause an accumulation of gum, etc., on feed-rolls, which will make a smooth finish impossible. In working rough, wet or snowy lumber, smooth feed-rolls will slip over the material without feeding it and make depressions. In order to avoid excessive pressure in feeding this class of stock, corrugated, sectional rolls should be used. On the other hand, care must be taken not to set the bottom feed-rolls too high, as nipping of the wood will result.

Insufficient or loose pressure bars or rolls for holding the wood down firmly when under the operation of the cutters will result in wavy, irregular cutting as the boards jerk alternately in and away from the knives.

A poor grade of output will result if cutter spindles are of too small diameter—if the heads are not properly balanced and in line—if shavings, chips, or dirt wedge between the cutters and the block—if bearings do not fit the spindles close enough, or are loose in their beds—and if the base and frame of ma-

chine is not strong enough to take up the vibration in working.

If the machine is of a make new to your experience, master its complete operation and adjustment before attempting to operate it. And then if you will observe the suggestions made above, you will save time, trouble and unnecessary expense in your planing and moulding work.—Yates Quality.

Mr. Cawkell Sees Signs of Encouragement

The Manager of the Furniture Manufacturers' Association Quotes Facts and Figures on the Situation in the Furniture Industry— What is Needed is Co-Ordination

An abstract of an address to the Hamilton, Ont., furniture retailers

There are in Canada according to government reports for the year 1919 some 270 plants making furniture, (including a number of small upholstering shops), and the capital investment represented is $25,000,000. The number of men employed is placed at 9,000, the wages paid, $8,000,000, and the sales, $25,000,000. The sales, it will be noticed are about the same as the capital invested. That is one big difference between the retail and the manufactruing branches of the business. Up until a few years ago, manufacturers did not turn their capital once a year. Now they are doing a little better than once a year.

Annual imports of furniture run less than $2,000,000. They are not on the increase, but, on the contrary, are rather less than they have been. The figures quoted include such lines as kitchen cabinets, refrigerators, etc., and also suites bought as samples by manufacturers.

Mr. Wm. Cawkell

How Furniture Sales Compare With Sales of Other Commodities

It is interesting to quote figures on sales volume in other industries to show how they compare with the volume in the furniture industry. Automobile sales run about $151,000,000 annually (at wholesale); amusements calculated on the theatre tax alone, $44,000,000; candies, $45,000,000; cigars, $75,000,000,—these as against the $25,000,000 sales of furniture. In the United States the sales of furniture are estimated at $5.75 per capita, which is about double the per capita expenditure in Canada. It is also true, that the per capita expenditure in the United States runs higher in other lines.

A feature of the situation with regard to the furniture industry is the rise in cost of materials. Commodity prices have risen 17 per cent since June, 1921. Cotton and steel have shown particularly strong increases, but there has been a stiffening in practically all lines. Cotton price increases affect all textiles used in the furniture industry, steel affects screws, nails, beds, etc.

One of the most important indices of industrial conditions is the record of commercial failures. These have been particularly heavy during the past few years of stress. The number of commercial failures in Canada in 1918 was 790; in 1919, 720; in 1920, 1050; in 1921, 2,400; and in 1922, until October 19, 2,939. The liabilities in 1921 were $73,000,000, while in 1915, the next worst year recorded, they were only $41,000,000. This big discrepancy is of course partly accounted for by the increase in commodity prices.

Signs of Recuperation

I believe that the worst of the depression is over and that we may look forward with confidence to better things. 1921 was a year of deflation, this year has been a year of recuperation, the beginning of the upward trend. Fundamentally conditions have improved. Everybody has got back to serious work. Waste and inefficiency have largely disappeared. Manufacturers have been putting their houses in order, and the efficiency in our factories has increased tremendously. Another encouraging sign is that two of our basic industries, steel and cotton, are likely to be flourishing. The cotton crop will probably be 25% greater than last year. The steel companies have increased their employees' wages 20%, which is a sure indication that they anticipate a labor scarcity.

Monetary Situation Improved

The monetary situation is also improved. The banks have decreased their loans. Money is cheaper—and is likely to be for some time—and cheap money means trade expansion. Loans for hundreds of millions have been subscribed in a few days. There is more money available than can be used. Consider in Canada how bonds have been bought up.

Retail merchants have got rid of their surplus stocks and prices are, in the main, deflated. The employment situation is improved. Last year at this time some reports showed 3,000,000 people out of work on this continent. Now it is stated, there are only some 500,000.

The railways will be making extensions and additions to rolling stock. There is a big car shortage which will have to be made good. Building has been going ahead remarkably in Canada this year—the greater part being residence work. At least 20,000

houses are being put up this year, and it is the new homes that are the biggest prospects for furniture business. Government figures show that in 1919 there was $30,000,000 spent in the construction of residences; in 1920, $42,000,000; 1921, $40,000,000, and in the first eight months of 1922, $71,000,000. The effect of this great building activity should mean an increased demand for furniture next year.

The furniture industry has big opportunities ahead. What we need is co-ordinated effort to take full advantage of them. Associations will help the retailers through the strengthening of selling forces, the elimination of unfair practices, the dissemination of information on cost accounting, etc.

Wide Use For Basswood

It Has Several Desirable Qualifications—Its Application to the Furniture and Millwork Industries

Basswood is a wood that has a very diversified use. In almost every line of woodworking it finds some sort of application, for it has several qualifications that make it very desirable. Its light color, light weight, good working and seasoning qualities, and the fact that it takes printing well are advantages that are put to good use in the manufacture of boxes and other containers, planing mill products and millwork, novelties and toys, furniture, pianos, and other lines of wood products. A very complete analysis of the utilization of basswood has been made by the U.S. Department of Agriculture, whose exhaustive report in this connection is abstracted herewith as being of interest to woodworkers who have occasion to make use of basswood.

Basswood is an important furniture wood because it glues well and takes and holds screws and nails very satisfactorily. It is well liked for such parts as drawer sides and bottoms, mirror backing, and shelves, because it does not warp to any great extent. Basswood is often used for the inside and hidden parts of expensive furniture. It is not generally used for outside work in furniture, because it lacks the strength of other woods, such as oak and red gum, and does not have an attractive grain or figure for finishing in the natural state. It is, however, used in enamel work, for which purpose it is well adapted, because it has a uniform texture, takes paint well, and, since it does not shrink and swell to any great extent, it is not inclined to crack the enamel coating as many other woods do.

Basswood serves well for cores of panels finished in expensive veneers. It is especially well suited for producing curved surfaces in furniture, because it can be readily bent into various forms by steaming, holds its shape after it is dry, and glues well. It is in demand, therefore, as a core wood for curved and irregular surfaces which are to be covered with figured veneer. Basswood is valuable also as core stock for large panels, because it can be obtained in large, clear pieces. Experiments on panels show that there is less warping when a low-density core wood, such as basswood, is used than with a high-density core wood. The low-density core wood has the additional advantage of making a light-weight panel. Basswood, also, does not split so readily as many other light-weight woods and holds the veneer well. In the gluing process basswood absorbs the glue very readily; therefore, a liberal amount of glue should be used in order to avoid a starved joint.

Planing Mill Products and General Millwork

Basswood has been a favorite wood for many years for planing mill products, sash, doors, blinds, and general millwork, particularly for inside finish, because it machines to a smooth surface when seasoned, keeps its shape well, and takes finishes extremely well. It is one of the best woods for enamel work because of its uniform, clear, light color, smooth finish, and even texture, which absorbs and holds the paint evenly and well. It also finishes well with other paints and varnish. There is a greater demand for figured wood for these products, such as that of red gum, birch, and oak. Much basswood is used, however, for interior woodwork, especially for ceiling and in the form of wide boards for finishing and panel work. On account of its adaptability to cutting with tools, basswood serves well for moldings and carved work in interior finish of various kinds. Much basswood is also manufactured into bevel siding, but it is not so well adapted to exterior work because of its liability to decay.

Rising costs of the upper clear grades have had much to do with discouraging its use, for the dark-colored and streaked material of the lower grades is much less valuable for these purposes. Yellow poplar, birch, and the softer grades of pine are now generally used in place of basswood.

Large Prizes for Essays on Economics

Actuated by the desire to advance the study, and more general appreciation of economics, Alvan T. Simonds, president of the Simonds Saw Company, of Fitchburg, Mass., and Chisago, Ill., proposed an essay contest open to pupils of high schools and normal schools in the United States and Canada. Mr. Simonds offers two prizes of $1,000 and $500 for the best essays written by students on the subject: "The Lack of Economic Intelligence and some of the Injuries it has Caused Individual and General Welfare in the United States since 1860." Mr. Simonds hopes this contest will interest many in the study of economics, who might otherwise pass it by. He also expects it will aid in creating a public sentiment that will result in the practical study of the subject in secondary schools as part of the training of every teacher. Rules governing the contest have been prepared, and persons interested may obtain copies of them by addressing the Simonds Economic Prize Contest, 470 Main Street, Fitchburgh, Mass.

Reduce Costs

The successful manufacturer must be always alert to minimize his manufacturing costs. One of the most conspicuous illustrations of this happened a few years ago in the automoblie industry, where hundreds of thousands of dollars' worth of machinery had to be sacrificed to the junk dealer because of the invention of new machinery which did the work faster, better and cheaper. The immediate loss on the old machinery couldn't be considered. It was cheaper in the end to throw it away and get the new machinery. Not to have done so would have been suicidal.

The Requirements of Pneumatic Systems

Table Gives the Sizes of Connection Pipes Generally Used With Woodworking Machines—Requirements Have Changed Owing to Improvements in Machinery

In laying out a pneumatic system for the collecting of dust in factories certain quantities must be chosen arbitrarily by the designer, and the success of the installation depends largely upon his experience. It is quite possible for an inexperienced designer to lay out a system which will apparently work properly, but this generally results in a great deal of power being wasted. The engineers of firms making pneumatic systems, who are thoroughly familiar with the theory and purpose of such systems, can determine by calculation and by reference to their past experience just what size piping and fan are necessary.

It is not only in new plants that attention should be devoted to economy of power, but also in those which have been in operation for a number of years, and especially where conditions have changed. There have been constant improvements in the art of dust-collecting, and it is often possible for us to secure appreciable power savings by making slight changes in piping, joints, layout, fans, speed, etc.

Requirements for woodworking systems have changed rapidly of late, and further changes are taking place every day. This is largely due to the fact that modern machines run at much higher speeds than formerly, and produce a volume of sawdust and shavings that is correspondingly greater. Naturally larger apparatus is required, and if old machines are replaced by new ones, the dust-collecting system should be enlarged to meet the new conditions.

Type of Machines		No. of Connections	Diameter of Pipe
Swing Saws	Small size on dry kiln lumber, large on wet	1	3½ inches to 6 inches
Rip Saws	Dry Kiln Material	1	4 inches
	Not Dry Kiln Material	1	4½ "
	Self-Feed Saws	1	5 "
Table Saws		1	4 "
	For Box Factory Work	1	4½ "
Mitre Saws		1	4 "
Variety Saws		1	4 "

Hog	12 inches wide and under		8 "
	Over 12 inches		12 "

The sizes of connection pipes required for a dust collecting system

The sizes of connection pipes generally used with woodworking machines are given in the adjoining table which is recommended by the B. F. Sturtevant Co. While the table gives the sizes of connections commonly used with woodworking machines, it is not intended to restrict the pipe to these diameters, as the size varies with the quantity of shavings, the kind of lumber, its condition, whether wet or dry, and the variation in speed of the cutter heads. Modern high-speed machines require larger connections than older types, even though the cutters be of the same size. Experience will dictate just what increase is necessary.

If the system handles material, such as chips, etc., branch connections should preferably be located on the side of the main. When placed on the bottom they may interfere with the flow of material past the the opening, and should flow be reduced by closing or partly closing a blast gate, the solid material is likely to drop into the branch and cause choking.

James E. Stark Dies in the South

James E. Stark, one of the largest manufacturers and exporters of hardwood lumber in the United States, died at his home in Memphis, Tenn., on October 19th after an illness of six weeks. Mr. Stark came to Memphis from Chicago, where he was one of the organizers of the Chicago lumber exchange. He was one of the organizers of the Southern Hardwood Traffic Association, and had for years been officially connected with the American Hardwood Manufacturers' Association, and had aided in the formation of the Hardwood Manufacturers' Institute.

After a machine is invented it takes continual thought and attention to obtain the best results from it.

Getting Box Costs Down to a Proper Basis

The Purpose of the Differential Price List and How it is Applied—The Fallacy of Quoting on the Per Thousand Foot Board Measure Basis —Practical Examples

Up to the present time there seems to have been no more comprehensive way of comparing or pricing wooden boxes than by the per-M-foot-board-measure basis. This method, however, does not take into consideration size, quantity, cleats, printing, fasteners, whole or pieced stock, grades, different kinds of wood, different thicknesses of stock from which boxes are manufactured, etc. Therefore, in order that a more exact basis of comparison might be derived, the National Association of Box Manufacturers have adopted what is called a differential price list which has been developed after a great deal of study in connection with the cost of manufacturing boxes of various kinds and according to various specifications.

A brief outline of the purposes and advantages of the differential list was printed in the last issue of the "Canadian Woodworker." This present article will further explain the system and by illustrative examples show how superior the differential method of figuring prices is over the per-M-foot-board-measure basis.

The Theory of the Differential Price List

No wood box manufacturer will question the statement that it costs more to produce a small box than it does one of medium size, nor will he question the fact that as you increase the size of a box above a certain point, the cost of production increases with the size. To visualize the cost range , Fig. 1 may be of assistance. The curved line should indelibly impress upon the manufacturer's mind the facts as just stated. Acknowledging that the cost of production, based upon the per M foot measure varies with the size of the container that is being manufactured, why should the box manufacturer persist in quoting prices based upon the amount of lumber used in the order, at so many dollars per thousand feet? The only answer to this question is that it is easier to quote a price measured in dollars per thousand feet than it is to quote a price on the individual box, especially if the order comprises more than one size. Strange as it may seem there is still another reason why the average box manufacturer quotes a blanket price on an order without giving consideration to the variation in side; he does not know the differential to apply to the various boxes that will correctly take into consideration the difference in manufacturing cost.

A wood box manufacturer that quotes on the basis of the per thousand feet contained in the order, and assuming that the quotation covers a variety of sizes, or, if he quotes a price "per box," based upon per thousand foot prices without considering size of the individual boxes, he is in either case securing too much or too little for some of the boxes in the order. There are pages of figures in the Differential Price List that are used in arriving at a base price per one hundred boxes, from which discount is to be taken, this discount to be determined by the user of the book, and to be based upon his production costs. The theory of the differential is shown in Plate 1.

Two sample pages of the differential price list are produced herewith. They are but typical of the 49 similar pages that the list contains and which give data for boxes of all dimensions and thicknesses of stock. The list is based on surface measure and each item gives the list price of each pair of parts or each four cleats on the basis of 100 boxes. The extra charge for replaning each pair of parts is also given. This extra charge is for surfacing the re-sawed part when boxes are to have smooth surfaces inside and out. In addition to the 49 pages of the type illustrated there are several pages of data relating to extras, including such factors as tying, the use of whole stock, the use of different grades than "regular," cleating, printing, fasteners, and the size of the order.

To illustrate how the list is used a specific example will be taken. Assume a box conforming to the following specifications: 30 x 18 x 16½ in.; style

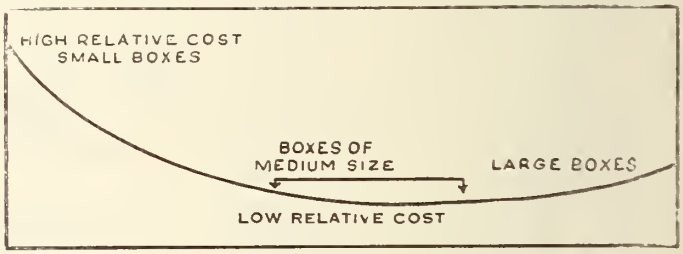

Fig. 1—This curve illustrates the principle at the basis of the differential price list

2; ends, sides, top and bottom 3/8 in.; cleats 13/16 x 2½ in. The following table gives the board and surface measure of each part and also the list price as taken from the differential price list.—

Cutting Size	measure Board	measure Surface	price List
Sides, 32-3/8 x 16½ in.	3.709	7.419	$24.55
T. & B., 32-3/8 x 18-3/4 in.	4.215	8.431	27.80
Ends, 18 x 16½ in.	2.063	4.125	14.11
Perpendicular cleats, 16½ x 5 in.	1.146	1.146	8.02
Horizontal cleats, 13 x 5 in.	.903	.903	6.35
	12.036		
Cleating (from table of extras)			3.00
			$83.83
Tying shooks (from table of extras)			2.51
List price			$86.34

In figuring box feetage, either board or surface measure, each pair of parts are treated separately—two ends, top and bottom, two sides, etc.

The example gives specifications for a style 2 box, a box having four cleats on each end. It is best, in order to eliminate unnecessary figures, to treat the two perpendicular cleats as one and likewise the two horizontal cleats. The cleats, being 2½ inches wide, show 5 inches on figuring sheet. The feetage for a pair of these would give the feetage for four cleats (either four perpendicular or four horizontal). This would give the feetage on the respective cleats for both ends.

The Differential List

We will assume that the foregoing box specification is one upon which cost and profit have been determined and that with lumber, labor, overhead and supplies costing a certain figure the box manufac-

turer knows he can sell it on the basis of $50.25 per M ft. B.B. and make a 10% profit. The problem then is to determine the discount that must be applied to the list price, as found from the differential price list, in order to secure the correct selling price.

As shown in the table above this particular order contains 12.036 ft. B.M. and the list price is $86.34. This is equivalent to $71.73 per M ft. B.M. The manufacturer, as indicated, can sell this box on the basis of $50.25 per M ft. B.M. and make a profit. The percentage off list to give $50.25 per M ft. B.M. is 70 per cent; or in other words, if a 30 per cent discount is applied to the list price as determined by the differential system, the price at which the boxes must be sold will be obtained. This same discount will apply to all other boxes regardless of size, style or extra operations with the assurance that the profit will be approximately the same in all cases, and it will not be necessary to change the discount until there has been a change in costs. Of course, it must be understood that each manufacturer must determine the discount that will apply to his own particular operations. No one discount can possibly apply to all conditions.

The Re-Sawed Box

There may be manufacturers today willing to quote the same price (on the per M foot measure) on 13/16 and re- sawed boxes. It costs less to manufacture one box having a total of ten feet of lumber. Regardless of this fact and the fact that it requires a better board for re-sawing than it does for the heavier container, many manufacturers are willing to give

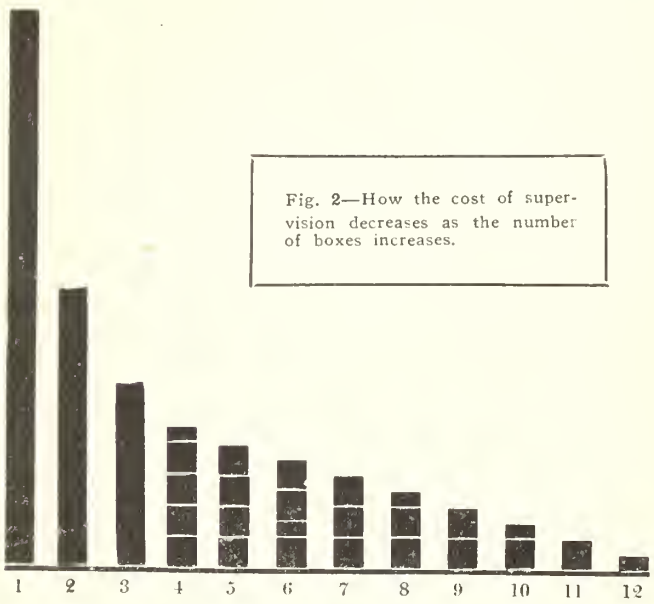

Fig. 2—How the cost of supervision decreases as the number of boxes increases.

13/16

Two specimen pages of the differential price list

the extra service and to close their eyes when approaching the waste pile.

In the table below are given the specifications for two boxes, box No. 2 containing one-half the footage of box No. 1. If a man were quoting on both boxes on the per M foot basis, there would be no differentation in the price when reduced to a footage basis. A base price has been shown for each size, the price being obtained from the Differential Price List, and shows an additional cost of 42 cents per one hundred boxes (gros) to cover waste, expense of re-sawing and extra handling. The difference of 42 cents in price per one hundred boxes in favor of box No. 2 would vary with the discount applied by the manufacturer, and as has been previously stated the sales price is determined by the individual manufacturer after considering his costs.

Box No. 1

Style 1—13/16" all round
24x12x6

	Cutting Side	B. M.	S. M.	List
Sides	25⅝x 6	2.135	2.135	$14.79
T. & B.	25⅝x13⅝	4.849	4.849	32.28
Ends	12 x 6	1.000	1.000	7.00
		7.984		$54.07

Box No. 2

Style 1—13/16" Ends, ⅜" S. T. & B.
21⅜x12x6

	Cutting Side	B. M.	S. M.	List
Sides	23x 6	.959	1.917	$ 6.68
T. & B.	23x12¾	2.037	4.073	13.78
Ends	12x 6	1.000	1.000	7.00
		3.996		$27.46

To the laymen it appears easy for the box manufacturer to ascertain true costs. To the manufacturer it is a difficult problem. It is not difficult for a box manufacturer to find his production costs for a given period, but such costs are based upon the total footage manufactured during the period and do not differentiate between the various orders that have passed through the plant. A manufacturer might show a profit for the time considered, and yet have lost money on one or more of the orders handled.

A manufacturer whose main business is the production of canned food boxes, piano cases or shoe containers would know the cost of producing such boxes, but when asked to quote on boxes with greater or less footage, of different style or additional operations, he would be making a serious error to consider the production costs to be the same at that upon his regular line of manufacture. Without precedent, the quotation on such an order would be based upon 90 per cent guess and 10 per cent fact. The differential price list applied to such a condition will give the manufacturer the correct quotation.

The construction of the differential price list is such that the manufacturer can take one regular line of boxes going through the plant and upon which costs have been determined. use this basis upon which to arrive at a discount to apply to the differential, and apply it to any order, regardless of size, style, kind of material or quantity, and know that he was receiving relatively the same profit as he received upon the order, the true costs of which were known.

Quantity Production

The city factory expects orders of one or more boxes for local delivery, and to quote a price per M feet would mean, if the price be based upon an average cost, that again the purchaser would be paying either too much or too little for his containers. The cost of changing machines for a small lot order must be considered; the increase in supervision charge, the cost of delivery, bookkeeping and collections are all items that must be considered, for in each item mentioned the cost of handling is no greater if the order be one thousand than it would be if for but one box, excepting the delivery charge.

Fig. 2, shows the rapid decrease in supervision charges as quantity in the order increases. This matter is handled by the Differential Price List, and the extra operations which are to be added to the gross price of the order before taking discount, will assure the manufacturer of quoting a proper charge regardless of the size of the order.

The cost of supervision must be borne by the number of boxes produced. If one box is ordered, the entire cost is borne by that box; if two boxes are ordered, the supervision cost is divided proportionately. This chart shows relatively the propotion of the supervision cost borne by each box as the number of boxes on the order increases.

The differential price list, as written, applies only to box shook. The made-up box factory can use it, for all made-up boxes are shooks. Until such a time as the cost of nailing shooks into made-up boxes has been considered and reduced to a differential and included in the publication, it will be necessary for each individual manufacturer to consider his nailing and handling costs, and add such costs to the shook selling price, as determined by the differential.

Cutting up Logs for Dimension Stock Tests

A carload of red gum logs for use in a study of the best methods for drying small dimension stock was recently received at the Forest Products Laboratory at Madison, Wis. The logs were furnished the Forest Service by the Kraetzer-Cured Lumber Company, of Greenwood, Mo.

The logs will be sawed into small sizes at the laboratory sawmill, and proper drying schedules will be worked out. Red gum stock was chosen for these experiments because of the trouble which its users have had to prevent considerable degrade in drying.

The laboratory wishes to show how dimension stock can be dried at the sawmills, so that woodworking factories can buy it kiln dried instead of in a green or partially dried condition or in the form of long lumber or logs. When the latter are remanufactured at the consuming plant the result is a large loss of material, increased expense for labor, and extra freight charges for the waste stock.

A problem in kiln drying the small stock is the method of handling the small pieces economically. Handling the individual pieces is too expensive. Plans are to bundle the stock as it leaves the saw, thus cutting down the amount of handling.

Three methods have been suggetsed for drying dimension stock in quantities: (1) drying solid bundles, containing about 10 board feet, (2) drying bundles which have been made open to air circulation by small stickers, and (3) throwing the small stock loosely into bins as it is sawed, then drying it by the binful in the kiln. The efficiency of the three methods will be compared.

About 15 kiln runs will be made in the laboratory experimental kilns, on three sizes of dimension stock.

Upholstering and Trimming

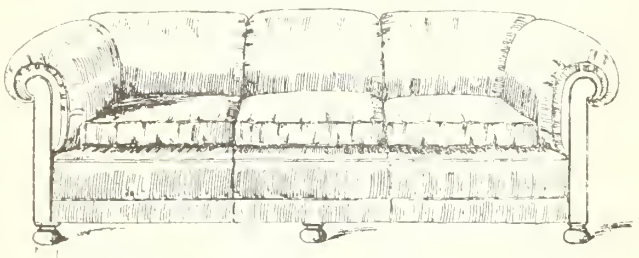
The Method of Upholstering a Chesterfield

The Same Principles Apply in the Treatment of the Larger Pieces of Down-Upholstered Furniture as in the Smaller Pieces

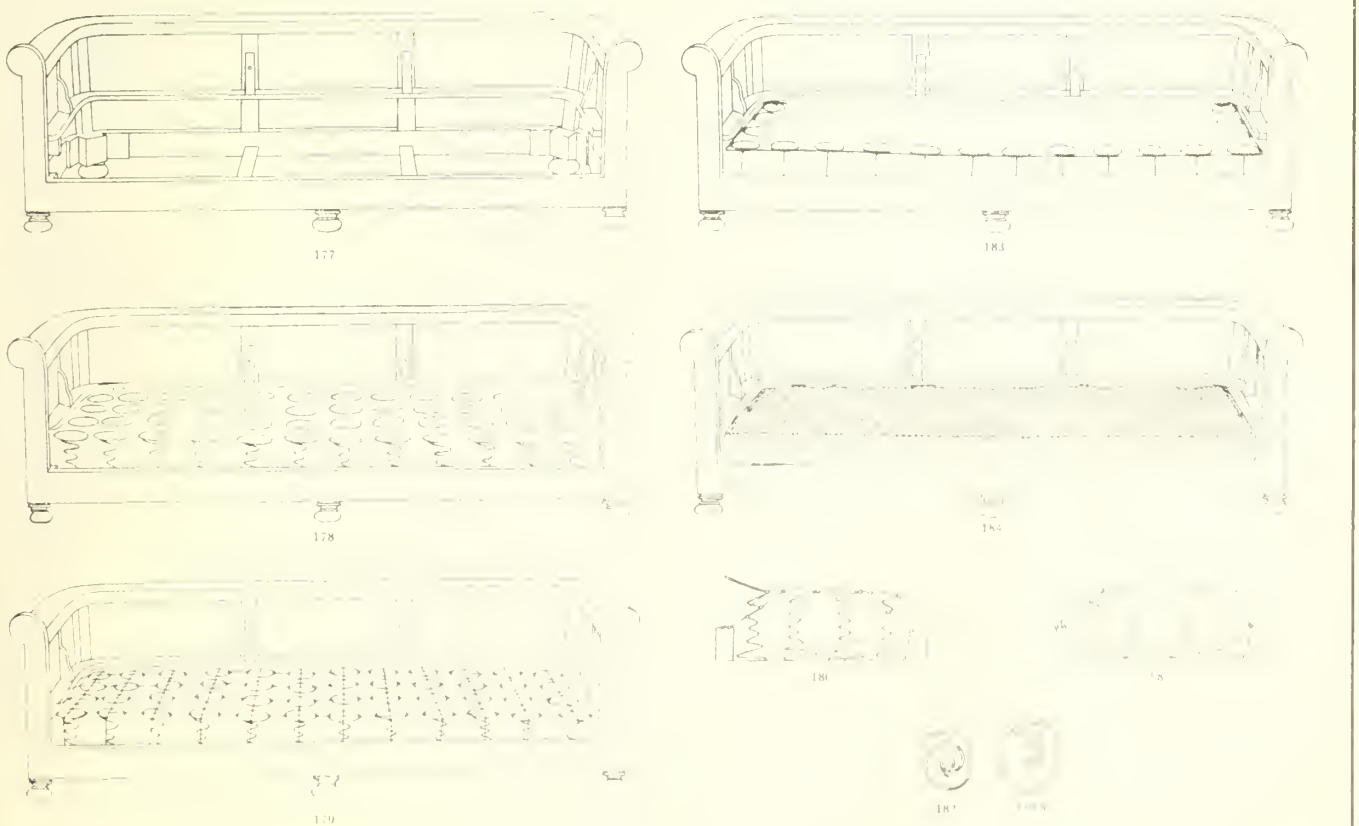
The larger pieces of down-cushioned furniture add a measure of complication to the work of upholstering, but are treated in practically all respects after the same manner as the smaller pieces. The Chesterfield illustrated at the bottom of this page is a typical example of a large piece employing down-top upholstering for seat cushion, arms and triple back, making with its deep-spring seat, spring arms and spring back a most luxurious piece of furniture.

The frame illustrated in Fig. 177, shows the general construction of the piece in question. This frame is webbed in the ordinary manner for 48 springs, placed in 4 rows of 12, as shown in Fig. 178. Prior to placing the first or edge row of springs, the top coil of each spring, which ordinarily appears as shown in Fig. 182, is opened and shaped as a long coil as shown in Fig. 182A so that it will project over the front rail. The end of the wire is also bent so as to lock in as shown in Fig. 182A. This elongated top coil is also bent so as to tip up after the manner indicated in the cross-section, Fig. 180.

The method of tying seat springs in spring-edge work has been covered in former articles of this series, but the details shown in cross-section, Fig. 181, will serve to recall the explanation. For those unacquainted with the preliminary processes of springing up, we would recommend the book "Furniture Upholstering" by John W. Stephenson, which explains at length the matter of placing and



The accompanying article describes the upholstering of this type of chesterfield



The various stages in the upholstering of a chesterfield

tying springs for spring edge, stitched edge and pillow edge work.

The next step is the attaching of the wire which forms the edge and in this case, as shown in Fig. 182, the wire edge is carried back on both ends so as to complete the cushion platform. Fig. 184 shows the burlap applied over the springs and stitched through and through back of the wire edge on the front and ends.

Our illustration does not show the springs sewn to the burlap, but on expensive work, such as this, it is customary to sew the springs to the burlap, knotting the twine at each stitch. Illustrations showing this process have appeared in connection with the pieces illustrated earlier in the series.

How Can Costs Be Determined in Advance of Manufacture?

A Question of Vital Importance to Makers of Upholstered Furniture—Faulty Cost Methods are Widely Used

At the recent annual meeting of the National Association of Upholstered Furniture Manufacturers, one of the features was an address on "Costs and How They May be Known in Advance of Manufacture," by W. L. Churchill, an industrial engineer of New York City. Mr. Churchill spoke in part as follows:—

When the Upholstered Furniture Manufacturers' Association asked me to tell them how to figure the cost of production in advance of its manufacture they disclosed one of the principle reasons for the limited adoption of cost determination by furniture manufacturers and they also call attention to one of the vital defects of typical cost collecting systems.

For the man or firm that attempts to determine the costs and proper selling prices of his products by collecting masses of detailed labor and material reports made out by their employees or by department clerks and foreman for them there is no way to determine in advance the cost of any new article proposed for production.

He can use his collected historical records of past performances on articles of similar construction as a guide in estimating, but the manufacturer who has had the experience of most furniture makers of getting estimates varying as much as 50 per cent—and that from the most practical of his foremen and superintendents—is not going to be satisfied with a cost system that fails him on this—too many vital details.

This failure of the typical systems, operated by collecting cost data from reports of current activities, is only one of the several weaknessess of this form of costing, although it happened to be an unusually dangerous defect for the furniture industry.

Prices Often Quoted Before Costs Determined

With frequent and radical changes in designs, styles, finishes, and even in types of furniture to meet the whims and fancies of a fickle buying public, it is frequently impossible for a manufacturer to get the benefit of even an experimental lot put through his factory before he establishes a selling price. He is even frequently called upon to quote prices from sketches, drawings and samples made by others.

When he sets such prices, that are subject to various determinations, according to who makes the estimates, he is facing two dangers: he may price too high, thus losing an opportunity for a satisfactory volume of profitable business that would be had if priced right, or the prices too low and gets a big volume of unprofitable business.

A costing method that does not give a cost in advance, and that will not get the same cost figures on any article no matter how many different persons may try to figure such cost, is not a satisfactory system for a manufacturer to use who has this problem to meet frequently.

A Wrong Principle

The whole difficulty is because of the acceptance and use of a faulty principle in costing. This principle is the attempt to saddle all the current changes in costs of operating and doing business upon the product that happens to be in process of production when these changes occur. Fluctuations in costs that are not due to anything inherent in the product are saddled on this process regardless of the fact that your customer insists upon a stabilized price. He won't pay you for the material or product that some careless workman may have spoiled; that has to come out of your profits. Why try to saddle the loss occasioned by that workman onto the particular chair he was making? Isn't it much better as a plain matter of management, to charge it to the account of the workman or his department, or to whoever is responsible?

When you will stop asking your accountants to compile costs by adding together all the detailed reports of workers, with their omissions, transpositions, errors and even falsifications, and instead furnish him standardized engineering costs details covering every unit and item entering into your products, then, and then only, can you figure your costs in advance of production. Such a step makes your accounting worth while, for it puts it up to one or a few trained people to supply accurate detailed information that cannot possibly be obtained from employee reports.

Introducing the engineering (or predetermining) principle into your costing means that instead of waiting for the completion of a lot of furniture to make a cost photograph you can make a detailed cost drawing in advance.

Mistakes Corrected Before Manufacture

When you get a cost photograph there is nothing to be done if the picture is unsatisfactory. Your money has been spent and the cost merely tells you that. With the engineering advanced detailed cost you are in position to revise, alter or adjust details until you have designed and developed the article to meet the cost and selling price requirements as well as those of appearance and service. It is much cheaper to make mistakes and correct them on paper in advance of manufacture than it is in the finished product.

It, of course, means the development and training of cost engineers to do this work for you as the supply of properly qualified people for this work is very limited. They are even scarcer than upholsterers; but, one engineer handles all the cost work for plants employing up to 200 people, and with the assistance of quite average type persons he can maintain a system for obtaining costs at less than 1per cent of your payroll and include estimating on new goods and all other work properly coming under the jurisdiction of costing for this insignificant trifle of expense.

Compare this factor of economy with that of high-

ly developed collecting cost system requiring a clerk for every thirty-five or fifty employees and with separate estimating and rate fixing forces and the further expense and annoyance caused by requiring employees to report their activities. The difference in cost of operation can easily become a 5 to 1 ratio, besides the greater accuracy, completeness and ability to cost in advance of production that the use of an engineer in costing offers.

In summing up, furniture men are urged to look into this principle thoroughly. It can well be the solution to their most vital problems. Those who have not already established costing methods will do well to investigate the value, economy and speed of installation of such a plan. One of its virtues it that it provides a plan for that capable son, nephew or other party that you desire to train into a thorough knowledge of the business.

The only way to figure costs in advance of manufacture is to adopt a method that figures costs on that basis. There is no makeshift that can be added to other methods that will accurately accomplish such results.

The engineer recognizes that the costs that you can and should pass along to your customers are practically fixed and subject only to revision with changes in market prices or in specifications of construction and methods of manufacture.

Knowing this, he wastes no effort collecting records of details. He does, however, tell you how much more rent you may be paying for idle space than you can charge into your products. He will tell you how much more or less you are spending currently for your goods than is the normal expectation and tell you what general costs you are wasting or gaining these amounts on.

When you send the boy to buy $1 worth of stamps and he loses them, the typical method of costing will tell you that fifty letters sent out cost 4 cents postage, as the cost of the lost stamps is placed on the letters for which they were purchased. The engineer, however, would have figured in advance that the letters would cost 2 cents each to mail and then would have said that the boy cost you $1 more than he should. The former cost report simply irritates you; the latter gives you a chance to correct a bad condition.

Discourage Sales of Mohair Covered Suites with Velour Covered Arms

At a recent meeting of the National Association of Upholstered Furniture Manufacturers at Chattanooga, Tenn., a couple of resolutions were passed, relating to mohair covered suites and to guarantees on imitation leather, which are of interest to all makers of upholstered lines. These resolutions are worded as follows:

"Believing that the manufacture of mohair covered suites with cotton velour covered arms is not to the best interest of the consumer, and, if continued, will react against our industry, we urge all members to educate their salesmen to discourage the purchase of such merchandise."

"As imitation leather has been used sufficiently long to demonstrate its wearing qualities, and, due to the fact that the guarantee has been much abused by many dealers, we recommend that all members who have not already done so, discontinue the guarantee of such covering material."

Reducing Finishing Costs

How High Quality and Lower Costs May be Reconciled—Many Economies Possible in the Labor Factor by Paying in Accordance With Production

By A. J. Cross.

The two main considerations in the finishing of furniture and other articles of wood are first, the quality of the finish and second, the cost. Of the two "quality" must necessarily take first place for upon it depends in no small degree the saleability of the finished product and to a certain extent the value and price which may safely be asked. While the cost of the finishing material itself and the labor involved in its application is proportionately small in comparison with the total cost of the completed article, it is doubtful if it is an exaggeration to suggest that a good finish adds anywhere from ten to twenty per cent. to the selling price. That is to say, that to take two articles identical in every respect and finish them with exactly the same material, only in one case doing a very ordinary job, while taking pains with the finishing of the second article so that what might be termed a quality finish is secured, the second item could command a price twenty per cent. in excess of the one which was just finished in a haphazard manner. Bearing these factors in mind the problem of reducing finishing costs, takes on added significance.

Quality Can be Improved and Cost Reduced

Actual experience has demonstrated that in the average finishing room the quality of the product can be improved and at the same time the cost of the work reduced. Such an accomplishment is doubly desirable for it not only enhances the value of the finished product but by reducing the finishing cost increases the spread between final cost and possible selling price. In doing this there are only two items with which to work, the cost of the material and the cost of the labor.

As it is essential that the quality must be maintained and even improved if possible, the idea of reducing the cost of the finishing materials does not appear to be very hopeful. It is true that small economies may be effected here and there through close attention to buying but this requires careful watching coupled with a thorough knowledge of the properties of the various items being purchased for the idea is not to buy cheaper material but to buy more cheaply. This may mean that in some cases it will be found advisable to pay more rather than less and yet be buying more cheaply.

When it comes to labor, there are many opportunities for effecting worth-while economies. In this, reference is not made so much to the use of modern equipment, and perhaps new and improved methods, as to increasing the productiveness of present equipment and methods. It is surprising what can be accomplished in this direction if gone about in a proper manner. For instance, the establishing of rubbing rates based on basic time standards resulted in a reduction of twenty per cent. in the costs of the finishing department of one large furniture factory. At the same time that this reduction in rubbing cost was secured, the quality of the rubbed finish was improved considerably. This was not accomplished by replacing hand rubbing with machine work, although the instructions called for the use of the rubbing machines on all surfaces to which they could be applied advantageously, but by the development of incentive rates on a fair and accurate basis, actually on minimum rubbing times as indicated on basic time standards.

Payment for Production

This is cited merely to show what has been accomplished. Working along the same lines, definite, accurate standards or rates can be applied covering all the finishing operations, including spraying as well as dipping, brushing, filling, sanding, etc. The payment of the labor employed in the finishing department by performance or production on rates that are permanent, accurate and fair, and which are based on minimum operation times, has long been recognized as desirable in every way but the trouble has been in the past that a definite basis upon which to establish such rates has been lacking.

Another point to consider is the placing of individual responsibility upon the shoulders of each workman. Not only should each finisher be held strictly responsible for his own work and penalized for faulty workmanship, but he should be held responsible for the quality of the work which has already been performed on the articles on which he works. This makes every finisher an inspector and has a surprising and extremely gratifying effect on the quality of the resultant finish and also on the number of rejects and repairs so often found necessary after the articles have been completely finished.

Each Finisher is Responsible for Good Work

This is developed in this way. Each finisher is called upon to carefully inspect each article before he does any work on it. If the preceding operations were not performed as they should have been he is to lay it aside and not put any time on it. Should he disregard this or through carelessness do work on articles that contain defects which could have been and should have been detected when it came to him, he is not paid for the time and work he put on each article afterward rejected. This means a lot, for usually a considerable amount of what should have been productive labor is thrown away on articles that are finally rejected. In this way this waste of costly labor and good material can be reduced to an appreciable extent.

These few suggestions barely touch the possibili-

ties for reducing costs that are to be found in the average finishing room. There is hardly an operation the productiveness of which cannot be increased by the application of good, sound commonsense coupled by a detailed analysis of every phase of the work and its bearing on succeeding operations. Past performances, either as to method or time, are not to be taken as a guide but each phase of each operation must be considered individually and collectively always with a view to increased output.

Is Your Finishing Department a Fire Menace?

The Possibility of a Serious Conflagration Should Emphasize the Advantage of Some Fire Protection Measures—The Manner in Which Gypsum Board Affords a High Degree of Security

By K. H. C.

The average finishing room presents very serious fire hazards. The very nature of the material used in this department—the oils, varnishes, etc.,—makes it essential to be always on guard, for these materials are very inflammable and once they are ignited, the flames are extremely hard to quench. The fumes and smoke which are generated contribute also to the difficulty of fighting the fire and instances are numerous of persons being overcome while attempting to put out fires arising from burning varnishes or other similar materials. In addition to a large quantity of inflammable finishing compounds, the average finishing room also contains a stock of furniture, cabinets or other wood products in various stages of completion. These, of course, fall easy prey to any flames that might arise. When once a fire starts to rage through all this mass of combustible material, it is quite possible that the flames will extend beyond the finishing room itself and will be ready to devour the whole plant, depending on the amount of resistance that is offered by the nature of the design and construction of the building. It does not tax the imagination, therefore, to picture a whole plant totally destroyed as a result of some little accident or act of carelessness in the finishing room.

Such serious conflagrations have frequently arisen, entailing heavy losses and the throwing of large numbers of workers out of employment. It is quite impossible to actually work out in dollars and cents the total loss that such a fire involves, for besides the well-defined and easily calculated loss of buildings, equipment and stock, there is loss of business, loss of time while a new plant is being erected, the loss that the firm have to face through not being able to meet competition, the loss that they may have to bear through their employees being hired by other firms, and other factors that cannot be computed in so many dollars and cents. It is obvious, therefore, that it is of the utmost importance for the owners of woodworking establishments to protect their property against fire, even against those fires that may seem insignificant, for who can tell when a spark may not be fanned into a very serious and disastrous conflagration.

Keep the Fire Localized

To guard against fires that may start in the finishing room and which, if allowed to spread, might cause the destruction of the whole plant, is then one of the most important matters to which the proprietor or manager of a woodworking establishment must attend. The inherent fire hazard of the finishing materials themselves cannot be avoided or overcome, but what can be done is to see to it that if any fire does start it will be confined to the immediate section of the plant in which it started. How can this be done? By using some form of fire resistive construction in the finishing room, so that a fire will be confined to that quarter of the plant until an opportunity is given for properly fighting and quenching the flames. This opens up the whole question of fire resistive construction. However, this article does not claim to exhaust the subject as applied to woodworking plants, but it will suggest the use of one tested and tried material—gypsum—as a fireproof agency.

Virgil G. Marani, an expert on the subject of fireproof construction, stated on one occasion: "It is a well recognized fact in fire prevention engineering that the fire hazard in construction regarded as combustible could be practically eliminated, or at least be reduced to a minimum, if the construction was of such character as to assure that an originated fire could be confined to its location of origin for at least ten minutes. The service of a fire department, or other means of extinguishing fire can, in the majority of cases, be obtained in much less time than the 'essential ten minutes' referred to. Construction requirements which will provide the 'essential ten minute' fire protection in combustible structures do not increase the cost of such."

Protection of this sort can be obtained by the use of incombustible lath and fire resisting plaster on the walls of finishing rooms—a type of construction that does not involve material increase in cost nor necessitate radical departure from present standard methods of construction.

Boards May Be Used Without Plaster

Any lathing material to be classified as "incombustible" must be of such character that it will not ignite or burn when subjected to fire. Present known materials which observe this physical requirement include metal lath in its various weights and forms and gypsum board. Gypsum plaster board might be termed "Incombustible Solid Lath" since the boards are erected in sheets which do not need to be perforated or distorted, in order to provide the mechanical key or clinch for the plaster, as is the case in other forms of incombustible lath.

The adhesion of gypsum plaster to gypsum plaster board is one of the remarkable characteristics of this form of incombustible lath. Repeated tests have demonstrated the high strength of the bond that exists between the plaster and the board.

Gypsum plaster boards alone (without the additional advantage of the plaster coats) afford an appreciable degree of fire protection wherever so used. For this reason a vast amount of gypsum boards have been used as wall surfaces without any plaster at all. The protection against fire has been all that could be desired. This is a type of construction that

may well be used in finishing rooms, although the use of plaster over the boards is superior.

Other uses of gypsum board without plaster include the following, all of which have some fire resistive application and are therefore of interest to the woodworker who is anxious to make his plant as fireproof as possible:

1. In the place of wood siding behind face brick or other masonry veneer, as an insulator.
2. In the place of wood siding behind the clap boards, as a fire stop.
3. Between wood siding and the clap boards of shingles, as a fire stop.
4. Upon the wood roof boards and under shingles or metal roof covering, as a fire stop and insulator.
5. Under the finished floor, or between the rough and finished floor, as a fire stop and sound deadener.
6. Within concealed air spaces as a fire stop.
7. As a fire protection to heavy timber (mill) construction, by being nailed direct to the wood members following the contour of the construction without creating concealed air spaces.

Gypsum Plaster Board a Low Conductor of Heat

The low heat conductivity of gypsum plaster board can be easily demonstrated by placing a small sample of the board, in a horizontal position, over a blow torch flame, and upon the upper surface of the board, place a piece of paper, a feather or other easily ignited and highly combustible material. So long as calcination is taking place it will be impossible to ignite the material placed on top of the fire test specimen. The insulation afforded by a 3/8-inch thick gypsum plaster board (without plaster) will prevent, for a period of about 10 minutes, the passage of sufficient heat, by conduction from the Bunsen flame, to ignite the highly combustible material on top of the sample. The temperature of a Bunsen flame averages about 1,800 to 2,100 degrees Fahr.

It is obvious from the foregoing brief reference to the properties of gypsum board that it is a material well qualified to give fire protection to woodworking plants and, more particularly, finishing shops. The makers of the product issue very explicit instructions regarding the method of handling it and by following these directions it is extremely easy to use it and thereby get a great measure of fire protection.

COTTON LINTERS
OF UNUSUAL QUALITY

Cotton Linters of guaranteed quality for the Mattress and Upholstering Trades. Quotations on this and our other lines—Cotton Waste, Reeds, Rattans, Turpentine, etc., will be gladly furnished on request.

Vertical Equipment Floor Space 4 x 6 ft.
Crated and shipped complete ready to set on the floor outside of your varnish room

YOU ARE PAYING FOR THIS EQUIPMENT—

while using old fashioned Varnish Drying methods.

The money you are losing will more than pay for this equipment in one year.

This statement is based upon a fact well known to manufacturers in every branch of the woodworking industry.

IT IS A COMPLETE UNIT of fan, motor, heaters, air compressor, with automatic humidity and temperature control.
is manufactured in sizes suitable to all requirements, both vertical and horizontal.
eliminates dust and dirt by the use of a new humidifying air washer without the use of sprayheads, pump and pipe connections.
will triple the output of your finishing rooms—practically eliminates sanding.
will decrease congestion in your factory.
will reduce investment of goods in process.
will improve working conditions for your employees.

"SET IT OUTSIDE YOUR VARNISH ROOM"

A. S. NICHOLS COMPANY

Aeolian Hall 33 W. 42nd St., New York City

Manufacturers of dryers for lumber, veneers, glued stock, varnish, paints, enamels, etc.

Increasing speed and reducing costs, while making certain highest quality work, in your finishing room with the

DeVilbiss
Spray-painting System

Whether you manufacture phonograph cabinets or chairs, metal cabinets or brass beds; whether you varnish enamel or lacquer those products, one DeVilbiss spray operator will do 4 or 5 times as much work as a brush finisher in the same time.

On every class and grade of work the sprayed-coating will be of highest uniform quality—free from brush marks, runs, fatty edges and like faults.

DeVilbiss exhausting equipment will insure a clean, healthful place in which to work, and reduce the fire hazard.

The outfit will be on the job every day, and cost little to operate and keep up.

These savings and advantages can be had in your finishing room, in the same profitable degree they are now enjoyed in thousands of wood and metal-working plants of every kind.

Let us mail you further particulars that meet your individual requirements

DeVilbiss Spray-painting portable equipment for spray-painting factory interiors and exteriors at a big saving in time and cost.

BeVeCo VENEERS

At the Markets

Look For The New Finish

"Brown Bird's-Eye Maple"

Different From Anything Ever Shown

AT the mid-winter markets you'll see this beautiful new finish. It is so entirely different from any thing you have ever seen. A rich, warm brown that contains the decorative figure with which nature has endowed this wood.

Two-tone bedroom suites, novelty furniture, decorative overlays and inlays—all respond to the use of Brown Bird's-Eye.

See for yourself. It costs you nothing to send for a panel showing the finish.

Your foreman finisher will know how to obtain Brown Bird's-Eye when you show him a sample panel. He can do it easily without additional equipment or materials.

Write or wire your finishing house for a panel at once. Or send to us direct, we will see that you receive a finished sample immediately. This of course, obligates you in no way.

Veneers and Panels

Why Some Modern Glue Rooms are Failures

Inexperienced and Incapable Help will Offset any Advantages that Up-to-Date and High Priced Machines Might Have

By R. N.

A glue room equipped with modern machinery and labor-saving devices would naturally be expected to be able to turn out first class veneering and panel stock. That there are other factors, however, involved in turning out quality veneering than the mechanical equipment of the glue room is a point often entirely overlooked. First class equipment certainly is a great aid in turning out a quality product; nevertheless, unless this is backed up with experienced glue room help, the most modern and highest priced machines will avail nothing in this regard. I have observed incident after incident where the best grade equipment has proven a dismal failure, as far as production and quality of the veneering were concerned, simply because the "ruling powers" could not or would not obtain the proper type of men to operate this machinery.

This brings to mind an incident which happened some time ago in the veneer department of a large plant. A glue-spreader of the home-made variety had been in operation until one day when the manager decided to cut labor costs by installing modern equipment. The new glue spreader, however, was not to the liking of the workman and superintendent, consequently, after a short time, they reverted to the old glue spreader, claiming that the new type was a failure as far as turning out good work was concerned.

Here was an instance where the machine was capable of living up to all the claims of its manufacturer, but the human equipment employed was not. For some reason the man operating the spreader failed to run the same successfully, resulting in an uneven spreading of the glue and dry spots. The amount of defective work turned out soon convinced the manager that up-to-date equipment was useless unless it was backed up with the proper human assistance.

Hand Presses Not Always to Blame for Poor Work

There are other plants where the volume of work turned out can easily be handled with a hand press; nevertheless, the manager often finds that he must get a power or hydraulic press if he wants to turn out good work. Why? Because he has been told by the foreman that his hand press never was made for that kind of work anyway. But the real fault generally is due to the fact that the glue room man may have a dislike for the labor required to do good pressing with a hand press.

It should be remembered that hand presses are often used in plants turning out the most expensive work, but to get the full pressing power out of a hand press, it is essential that pressure be first applied from the center screw, and this must come gradually to force out the surplus glue towards the edges. When screws are first turned down full pressure should not be exerted at once, as this generally results in a flooded glue joint. A few minutes should elapse before applying full pressure. This gives the stock time to adapt itself and the surplus glue will come out, making a first-class glue joint. When complaint is made that it is impossible to do good pressing with a hand press, it generally will be found that the fault lies with the crew entrusted with its operation and that full pressure is being applied in one operation. No matter how rigid a press may be made, there will be some loosening up due to the flattening out of the wood fibre and if care is not taken in going over the screws, as the stock becomes adjusted to the pressure, loose veneers or blisters will be the result. The press will be blamed for the bad work, but the fault is not with the press, but rather with the screw.

Incapable Labor Will Ruin Good Equipment

On another occasion, the manager of a woodworking plant equipped his glue room with the most modern equipment available. He put in the highest priced and latest machines throughout, but inside of less than a year the total equipment was fit for the junk man, as far as turning out good work was concerned. Having bought the best on the market, the manager thought any inexperienced man could operate it and turn out good work. Changes in the glue room help were frequent and when I looked over this modern veneering department shortly after, I found that the glue heater was leaking and mixing water with the glue. The glue retaining troughs on the glue spreader, being of copper, were badly battered, so that no steam could be admitted to keep the glue warm while in the spreader, while the new hydraulic press was a wreck, the plunger on the press leaking so badly that the press barely held up pressure until the retaining rods could be applied. In short, this modernly equipped glue room was a dismal failure after a few months' operation.

If the manager of this plant had insisted on engaging a glue room man in the beginning who knew how to handle and operate good equipment, he would undoubtedly have reason to be proud of his glue room. But trying to save a few cents by engaging help who knew nothing about glue machinery operation was the fatal mistake.

Modern glue room equipment will always pay good profits, but only when handled by an efficient and capable crew.

Dovetailing is work which, to give satisfaction, must be done with a high degree of accuracy to insure a neat fit and a good glue-joint.

Is Balanced Construction the Solution?

What Will Eliminate the Warping Troubles that are so Frequently Met with in the Use of Plywood?—Keep the Material Straight and Control its Drying so as to Prevent any Moisture Interchange

By M. N. W.

Warping is one of the troubles most frequently encountered in the production and use of plywood. This is true to such an extent that the impression that warping is a troublesome but unavoidable evil is held in many quarters and for this reason little if any attempt is made to eliminate this trouble or at least to reduce the loss incurred because of warped and twisted stock.

Usually when a certain trouble is tolerated or accepted as inevitable, no attempt is made to overcome it. This holds true in most lines of endeavor and woodworkers are no exception to the rule; in fact owing to the conservatism which pervades this industry, ideas, like old customs and practices, are held with unusual tenacity. This held true with regard to kiln drying practice and losses, and may be seen in many other phases of woodworking as practiced to-day.

The Cause of Warping

Warping, whether in solid wood or in plywood, is usually caused by uneven stresses and strains set up during the elimination or absorption of moisture. The wood "usually" is included because warping may be caused by what might be termed mechanical means, in contra-distinction to natural causes; for instance warping due to an irregular distribution of sticks in a pile of drying material or in plywood, piling panels on an uneven foundation. Uneven stresses and strains are due to a number of causes, such as unequal drying in various parts of a panel, uneven distribution of fibres in the various layers which go to make up a piece of plywood and unequal pulls due to using wood of varying densities and strengths in opposing parts of the same piece.

This is the reason for the claim often made that warping and twisting of plywood may be eliminated by so constructing each piece that the various stresses and opposing stresses are equalized and naturalized. This means that a panel made with certain face stock should have a piece of wood of equal strength on the back. In this way the pull on one side would be counterbalanced by an equal strain on the other side. However, the variables in wood are too great to ever accomplish much in this direction for it is practically impossible to build a panel in which all the stresses and strains would be counterbalanced and equalized. Further, were such a construction practical all our fine calculations would be upset, unless the absorption or elimination of moisture occurred with absolute uniformity over all faces of the stock. There is this to be said for this idea, however, and that is, that it is far easier to keep a piece of plywood straight if attention has been given to its construction with a view to having opposing plys of nearly similar strength and texture.

From the foregoing it will be seen that something more than balanced construction is needed to eliminate warping and twisting. Theoretically the idea may be sound but it is not capable of a practical application and unless all conditions were ideal little would be accomplished in any event.

Some other angle of approach must be sought to the question of how to prevent warping. Lumber, either solid or built-up, sets when it dries and tends to retain the shape in which it was dried as long as there is no appreciable change in the moisture content of the piece. This is in line with the suggestion that warping and twisting usually occur when wood is either giving up or taking on moisture. If we can keep the stock straight when drying it and then see that the moisture content of the piece is held constant, we will have solved our problem.

Now we seem to be getting near what promises to be a practical solution. Holding the material straight and flat while drying does not present any real problem for it is merely a matter of piling and of seeing that plenty of sticks are used, and that they are placed properly, one above the other in regular rows. This is accepted as good practice in most plants, but it is a point that will stand emphasizing for it is important. It is necessary for the piles to be constructed properly to ensure straight, dry stock.

Keeping the Material Straight

Have our material straight and dry, how can we keep it in that state? Perhaps a coat of paint or varnish might serve to preserve what moisture may be in the stock and to prevent more being picked up. But no, experiments have demonstrated that the average woodfinish is not moisture proof, and while it might retard the flow of moisture from air to stock or vice versa it would not prevent such a movement. This is not to be used as an argument against finishing both sides of an exposed surface, but merely as a statement of fact. How then can we prevent this interchange of moisture?

It is known that when the moisture of wood comes in equilibrium with surrounding conditions and that as long as such conditions do not change, the moisture content of the wood remains constant. Then by drying our material to some predetermined point and then controlling the conditions with which the stock is afterwards surrounded, have we not solved our problem? Even now, though, we are faced with difficulties. While it is possible to control conditions in a furniture factory, an attempt to do so would involve an expenditure of no small proportions and might be considered to be carrying theory too far.

Perhaps a compromise could be worked out that would be a vast improvement over present methods. Suppose we determine the average E.M.C. of conditions in the plant, that is, the average moisture content that the stock reaches as it comes into equilibrium with the varying conditions encountered in the factory at different seasons of the year, and then dry all our material, solid as well as plywood, to this point; have we not then reduced to a minimum the tendency to pick up or give off moisture and with that the tendency to warp and twist? It looks like it.

Is Balanced Construction the Solution?

(Continued from page 80)

Warping and shrinking may be reduced to a considerable extent by seeing that the stock is held true and flat when dried and that it is dried to the average E.M.C. of the conditions prevailing in the plant. In drying down to this E.M.C. it is a case of where too dry is as bad as not enough. If the E.M.C. in a plant is found to be seven per cent., then all material should be dried to seven per cent. and not lower. If the drying is carried beyond this point the material will pick up moisture which is as bad as giving up moisture as far as warping and twisting is concerned. In other words, to eliminate all movement in our stock we must reduce the drying operation to an exact science based on the average E.M.C. of conditions in the plant.

A Big Contribution to the Industry

No one has done more to develop and popularize the new brown finish for bird's eye maple than C. J. Byrns, general manager of the Bird's Eye Veneer Company, Escanaba, Mich., a firm that, as its name indicates, specializes in the manufacture of high grade bird's eye maple veneer. An article in the last issue of the "Canadian Woodworker" drew attention to the decided trend on the part of furniture manufacturers to use bird's eye maple once more. Already a considerable demand for furniture of this

C. J. Byrns

wood has been noted, the growing popularity being due to some of the new and beautiful brown finishes that have been developed. Bird's eye maple has always been recognized as a fine wood of considerable intrinsic merit and while certain disadvantages have grown up in years past, it seems that these have now been successfully overcome through the development of finishes that are bringing bird's eye into considerable vogue at the present time. How all this has come about forms a very interesting story.

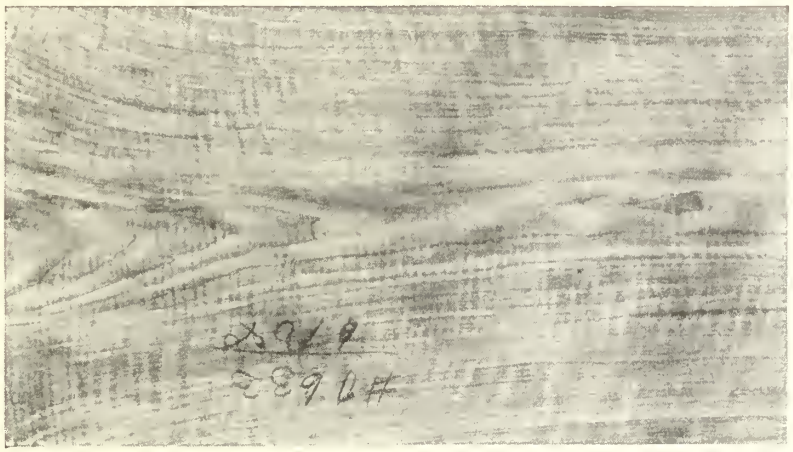
It appears that Mr. Byrns has been keenly interested in the conservation and improved utilization of birch and bird's eye maple. During many years of close observation, he learned that in the manufacture of natural bird's eye maple, much timber was being wasted because large quantities of slightly defective logs were unsuited to the production of the highest grade stock. While these logs were of good figure, they showed small black spots and stains which disqualified them for high grade veneers. Mr. Byrns, after a thorough study of the situation, came to the conclusion that a great deal of this waste was needless and he sincerely felt that much of this timber could be manufactured into quite beautiful and substantial furniture and interior trim. Just how to use these slightly defective logs in this way was a problem that Mr. Byrns tackled with unusual vigor. He consulted with an expert chemist with the result that certain pigments were compounded in certain oils and other liquids to produce an exceptionally handsome brown finish which has been called "BeVeCo Brown Bird's Eye Maple." Reports indicate that this finish has immensely popularized bird's eye maple and increased the demand for furniture manufactured from it. Stock that is slightly defective in any manner need not be wasted but can be cut and transformed, through the use of this new finish, into handsome pieces of furniture of exquisite interior trim.

President of Bird's Eye Veneer Co. Passes Away

The passing of J. C. Kirkpatrick, president of the Bird's Eye Veneer Co., Escanaba, Michigan, removes one of the most widely known men, both in Canada and the northern States, connected with the veneer and panel industry. Mr. Kirkpatrick had been ill for several weeks and the news of his demise was received by his many friends with profound regret. He was in his 61st year. As a youth he came with his parents to Palmer, Mich., where he became connected with his father in conducting the business of the Pittsburgh & Lake Superior Iron Co. In 1881 Mr. Kirkpatrick moved to what is now the village of Whitney, Mich., where he assumed charge of the iron company's lumber business at that point. Since then he has organized several well-known industrial and financial enterprises including the National Pole Co. and the Bird's Eye Veneer Co., both at Escanaba. The latter firm has attained international prominence under the generalship of the late Mr. Kirkpatrick and its product has found its way into the decoration of many Canadian homes by reason of its exceedingly fine texture and the soft and delicate beauty of its figure.

Officers of the Veneer and Panel Mfrs. Association

At the meeting of the National Veneer and Panel Manufacturers' Association, held at the Auditorium Hotel, Chicago, Ill., on December 5 and 6, Harry E. Kline of the Louisville Veneer Mills, Louisville, Ky., was elected president. C. J. Byrns of the Bird's Eye Veneer Co., Escanaba, Mich., was chosen treasurer. H. Brooke Sale is the retiring president.



C.L.WILLEY COMPANY

The Largest Veneer Plant in the World

FLITCHES

TWO HUNDRED years ago a titled Englishman provided in his will that his estate should offer a flitch of bacon once a year to any young couple who, having been married at least a year and a day, could swear that they had never quarreled.

The record is that in these two centuries only ten couples have claimed the flitch.

Yorkshire people, who are notable for their sense of humor, are proud to quote an ancient rhyme which claims a flitch of ham as part of their coat-of-arms. Doubtless this rhyme had its origin in some comical tradition like the story told above.

Flitches of beautifully figured wood are even more important to civilization than flitches of pork.

A saw, a knife, and a flitch of wood could well be the coat-of-arms of C. L. Willey Company, the greatest makers of veneer in the world.

The Lumber Market

Conditions in the hardwood lumber line are seasonably quiet during December and there are few sales transactions. Manufacturers, wholesalers and large consumers do not care about adding to their stocks beyond the necessary immediate requirements, as they naturally desire to keep down supplies when approaching the inventory period. It is expected, after the furniture and automobile shows are over, which will be toward the end of January, that these heavy consumers will be able to gauge conditions and get a line on how their trade is likely to shape up during the coming twelve months.

The outlook is getting brighter all the while and there are more inquiries for stocks. Millmen, who are taking out a quantity of hardwood, say that a demand is presenting itself on all sides which is quite a different state of affairs to that prevailing twelve months ago. The fall months have shown growing activity, and were it not for the car congestion and embargoes at certain points, distribution would also be on a satisfactory basis.

Stocks are lower now than they have been for some time; there are more requisitions for the lower ends and, with the expected industrial revival, hardwoods should begin to move again at a figure perhaps slightly in advance to which now obtains. Prices all along the line are getting stiffer, especially in the better grades of two-inch and thicker stock.

A good line upon the situation is furnished in a recent interview with a leading manufacturer who says that the stock they are carrying at present is about 40% less than it was a year ago. Logging expenses are about 20% more than last winter owing to the increase in wages.

1923 should be a year of normal activity and steady demand. No one wants to see a runaway market or any other untoward feature which would retard the growing call for hardwoods or undermine the spirit of optimism which now prevails.

Generally speaking, 1922 was a year of softwoods turnover rather than hardwoods, the former being brought about owing to the great building activity in all the larger centres, while the industries that consumed hardwoods were only running on part time schedules. Then most of the building was in the nature of houses, garages, apartments and business blocks rather than industrial extensions and new factories.

Outside of hardwood flooring, the manufacturers of which have been busy for some months, there was not that usual call for hardwoods which is seen when piano, gramophone, furniture, wagon, interior trim and other woodworking plants are operating to capacity. The expected revival in most of these industries is well on the way, and there is no doubt that things are now headed in the right direction and, with patience, perseverence and conservatism, the woodworking and hardwood trades, during 1923, should show a greater measure of turnover, satisfaction and profit than was experienced in 1922.

The box and crating manufacturers are getting to be the largest consumers of lower grades with the result that these are decreasing in supply. Quite a number of big consumers are endeavoring to contract for their requirements extending over the first half of 1923, but manufacturers in most cases do not care to enter into any engagement involving such a long committment.

Stock Selling Concerns

Toronto, Ont.,

Editor, "Canadian Woodworker,"

We manufacture a line of wood novelties that is finding a very ready market and we have in mind enlarging our company's facilities and increasing its capital so that a very vigorous sales policy may be adopted with the object of marketing our products on a very large scale. Can you give us the names of any financial firms that may be interested in selling our stock and thus helping us to finance our venture?

Yours very truly,
G. E. L.

There are undoubtedly a large number of firms that will be glad to look into a proposition of your kind and sell the stock if they are satisfied that your venture will be successful. We would mention definitely Anderson, Robinson & Co.; L. M. Green & Co., and Stewart McNair, Reid & Co., all of Toronto.

Floor Lamp Manufacturers

Memphis, Tenn.,

Editor, "Canadian Woodworker,"

We would highly appreciate your furnishing us with a list of Canadian floor lamp manufacturers.

Yours very truly,
M. V.

The following is a partial list of table lamp manufacturers:—Adams, Cruden, Adams Co., Toronto; Art Lamp & Shade Mfg. Co., Montreal; Baetz Bros. Specialty Co., Kitchener, Ont.; Brantford Pattern Works, Brantford, Ont.; Brantford Willow Works Co., Brantford, Ont.; Canada Furniture Manufacturers, Limited, Woodstock, Ont.; Crevier & Fils, Montreal, Que.; Imperial Rattan Co., Goderich, Ont.; North American Furniture Co., Owen Sound, Ont.; J. V. Watson Furniture Co., Kincardine, Ont., and W. E. Whitehead, Toronto, Ont.

Woodenware of Basswood

Basswood is made into articles of woodenware used in the shipment of provisions, such as pails and tubs. It is well liked for such uses, because it is light in weight and odorless, and the light color of the wood makes a good appearance. On account of its good working qualities, it is easy to manufacture into such products. It also has the advantage of showing stenciling extremely well. The light weight of the wood effects a large saving in freight, both when shipped empty to the purchaser and when filled with provisions.

News of the Trade

The American Walnut Furniture Co., Montreal, recently obtained a charter.

The Nagle Upholstering Co., Stratford, Ont., recently suffered a loss of $500 by fire.

The Security Box Co., is a recent registration at Montreal. Jos. M. Laberge is the principal.

The Dougal Varnish Co., Manufacture St., Montreal, are adding one storey, 12 x 35 ft., to their factory.

The Dominion Upholstery & Manufacturing Co., 392 Notre Dame, Winnipeg, is a new concern recently incorporated.

A new factory for the manufacture of auto trucks is in the course of erection by A. H. Wagstaff, 302 Greenwood Ave., Toronto.

McAuliffe Davis Lumber Co. Ltd., Ottawa, Ont., will start work shortly on an addition to their woodworking plant on Chamberlain Ave.

Coulter Wood Products, Ltd., 40 Park Row, Hamilton, Ont., have started the erection of a one-storey drying shed, 20 x 20, at a cost of $1,000.

Scott Lumber Co., Ltd., Port Arthur, Ont., is a new concern with a provincial charter to manufacture and deal in wood products. Capital $50,000.

Radford-Wright-Wilson Co. Ltd., Winnipeg, general woodworkers, have filed application to change their firm name to Radford-Wright Co. Ltd.

The B. C. Manufacturing Company of New Westminister recently shipped 30,000 bundles of fruit box shooks to Australia by the Canadian Highlander.

The Guelph Carriage Top Co. Ltd., Guelph, Ont., have been granted supplementary letters patent to change their name to that of John Mitchell, Ltd.

Brompton Lumber Manufacturing Co. have been granted supplementary letters patent to increase their capital of $249,000, by creating 2,000 shares of 100 each.

Martin Orme, a director of Orme, Limited, Ottawa, manufacturers of pianos, phonographs and other musical instruments, died recently at the age of 31.

The sash and door plant of Jas. Limoges, Terrebonne, Que., was completely destroyed by fire recently, entailing a loss of $50,000. The owner expects to rebuild.

The Eastern Billiard Table Co. Ltd., Montreal, is a new firm recently incorporated, to manufacture and deal in billiard tables and accessories. Capital $50,000.

Cutten & Foster, Church St., Toronto, manufacturers of automobiles, carriage tops, and accessories, are preparing plans for a two storey addition to their plant.

Jos. Creighton Woodworking Co., 701 Central St., London, Ont., recently secured the millwork contract for the new factory of the London Shipping Containers, Ltd.

W. M. Byens Gananoque, Ont., one of the largest stockholders in many of the town's manufacturing plants, including the Ontario Wheel Co., died very suddenly recently.

A recent report from Brantford, Ont., that the National Casket Co., Toronto was preparing to remove to the former city has brought forth a positive denial by the company officials.

Francis & Dane, Ltd., Hamilton, Ont., is a recent incorporation, under provincial charter, with a capital of $200,000, to manufacture wooden cases, trunks and other similar products.

Merritt Bros., basket manufacturers, Grimsby, Ont., have started work on their new warehouse to cost $4,000. The new building will be two storeys, 32 x 45 ft., of frame construction.

The installing of a planing mill is contemplated by Wm. Zurbigg, at Rannoch, Ont. The owner has entrusted J. H. Jameson, St. Mary's, Ont., with the installing and equipping of the plant.

The plant of James Davidson's Sons, Ottawa, Ont., general woodworkers, is expected to close down around Christmas, for three weeks, for the purpose of making necessary repairs.

The Robert Johnston Motor Co. Ltd., Sault Ste. Marie, Ont., have been granted a federal charter to manufacture and market trucks, aeroplanes, water craft, etc., with a capital of $100,000.

Canadian Public Booth Company, Ltd., Ottawa, is a recent incorporation under federal charter, to manufacture and deal in all kinds of furniture and furnishings fittings. Capital $50,000.

The Streetsville Lumber Co., with mill at Streetsville, Ont., and offices at 131 Front St. East, Toronto, Ont., are installing a class D, Sidmon lumber curing kiln to dry their heavy door stock.

Gilbeys Distillery, in Scotland, has recently instructed its Canadian representative to purchase large quantities of box shooks in British Columbia. Hitherto this business was placed in Norway.

Quebec Hardwoods, Ltd., have their offices at 211 McGill St., Montreal. The Company of which Mr. J. W. Harding is managing director, does an export and domestic trade in hardwood.

The box shooks being manufactured in New Westminster, B. C., are finding a ready market in the large Australian cities, Adelaide and Melbourne. Heavy shipments have been made of late.

Paul & Greaves, Verdun, Que., have secured the sash and door contract for apartments on Lasalle Rd. J. P. Dupuis, Ltd., Church Ave., have secured the interior trim contract for the same buildings.

The Grey Furniture Co. Ltd., Neustadt, Ont., have added another storey to their present plant, which is 100 x 60 ft. They are manufacturing medium grade bedroom furniture and a line of library tables.

The new pipe organ for Knox Presbyterian Church Cranbrook, B. C., which is now being installed, was manufactured by Casevant Freres, St. Hyacinthe, Que. The cost of the instrument was $4,000 complete.

Moore Bros., general woodworkers, 23 Wayland Ave., Toronto, are putting in the foundations for their new plant, which they intend moving into about the new year. The building will be one storey, 60 x 75 ft.

A sad accident occurred at the Ball Planing Mills Co., Barrie, Ont., when Fred Glynn, a carpenter, broke his neck when a ladder, on which he was working, collapsed. Deceased leaves a widow and a large family.

Robert Lyons, former manager of the Wood Products Company, Parry Sound, Ont., lost his life in the North Sequin River recently when he broke through the ice when returning from inspecting some game traps.

HAY & CO., Limited Woodstock, Ont.

the old power plant owned by Barkey Bros. The firm is making immediate preparations to get under production on fire engines for which there is a large demand.

American Chemical Paint Co., Windsor, Ont., were recently granted a provincial charter to manufacture and deal in paints, oils, polishes and other similar ingredients in the province of Ontario. $40,000 is the authorized capital.

John Bailes & Sons, Ltd., Oshawa, Ont., is a new concern recently incorporated with a provincial charter to manufacture and market trucks, farm implements, flying machines and other similar products. Capital $100,000.

The Gibbard Furniture Company, Limited, Napanee, Ont., are enlarging their plant by a two-storey addition, 60 x 120 feet. They will install a new power plant and put in additional machinery during the winter and spring.

Kenchan Wagon Co. Ltd., Montreal, is a new firm recently incorporated to take over as a going concern the business known as James Kenehan, makers of wagons, carriages, sleighs, trucks and other vehicles. Capital $60,000.

Paragon Products, Ltd., Toronto, were recently incorporated to acquire the firm known as the Paragon Dishwasher's Syndicate of Canada, and to manufacture and deal in washing machines and furniture of all kinds. Capital $750,000.

Stuart Bros. Ltd., Hamilton, Ont., were recently granted a provincial charter to manufacture and deal in sash and doors and other builders supplies. Capital $40,000. Among the incorporators are A. Stuart and J. Stuart, builders, both of Hamilton.

James Carr has started a planing mill business at Allis-ton, Ont., and is ready to manufacture all the milling requirements of the building trade. He intends extending his premises and installing additional machinery to handle the increasing business.

W. G. Quast, manager of the Saskatoon branch of the Knechtel Furniture Co., was a recent visitor to Winnipeg. He states that there is a decided improvement in the West especially so in the larger cities and anticipate big business for the new year.

W. I. Henry, well known lumber merchant, now operating a retail lumber yard and planing mill at Flesherton, Ont., is selling out his interest in this business owing to ill-health. The concern has done very well and at present is enjoying a splendid business.

W. D. Patchell, of Midland, Ont., has recently opened a factory for the manufacture of wood specialties of all descriptions. It is well equipped with the necessary machinery and Mr. Patchell, who is well-known to the trade, states that business is very good.

Chappells, Limited, Sydney, N.S., are considering the installation of some new machinery, in particular equipment for the manufacture of hardwood flooring, which will be a new product for them. They are also thinking of putting in a new endless belt or drum sander.

J. P. Abel Fortin, Limited, Montreal, have added a few machines to their wooden box plant and are commencing the erection of another warehouse. They are specializing on doors and trims of British Columbia fir and are planning to increase their output in these lines.

The Beattie Automatic Phonograph Co. Ltd., Youge St. Arcade, Toronto, were recently granted a charter with $500,-000 capital, to manufacture and market phonographs. Location of their new plant has not yet been decided. The managing director is Geo. B. Beattie, Toronto.

The English Lake Lumber Co., Lake Frontin, Que., is a new company incorporated to take over the mills and limits of Murray & Gregory, Limited. St. John, N. B. The new company will erect a large plant for the manufacture of tubs, pails and boxes for the American market.

At the annual meeting of the Cockshutt Plow Co., Brantford, Ont., the following officers were elected: President, His Hon. Col. Harry Cockshutt; first vice-president and general manager, E. A. Mott; second vice-president and works manager, G. K. Wedlake; secretary, E. Sweet.

The Gold Medal Furniture Manufacturing Co. Ltd., Toronto, have taken over the " Farabed" for Canada and expect to find a large market for it. Comfort, adaptability and strength are said to be features of the new bed. Various grades of mattresses are supplied to fit the bed.

Puddicombe-Irvine, Limited, Toronto, is a new company with a provincial charter to manufacture and market motor boats, motor cars, flying machines and other conveyances. Capital $100,000. Two of the incorporators are, R. M. Puddicombe and R. A. Irvine, both of Toronto.

The Border Cities Casket Co. Ltd., Ford City, Ont., is a new company recently incorporated to manufacture and market caskets, cabinets and all kinds of furniture. Capital $40,000. Two of the incorporators are Charles De Saubier, manufacturer and T. Mogillo, cabinet maker, both of Ford City.

The rapidly growing business of Paul Bros., of Shelburne, Ont., operating a retail lumber yard and planing mill, has compelled them to extend their premises. Their planing mill will be enlarged and additional machinery installed, these increased facilities to be ready by February 1, 1923.

At a meeting of the creditors of Panels Ltd., which company recently made an assignment, a settlement was affected and the company was reorganized as the Southampton Plywood Works, Ltd. The office at Toronto has been closed and in future the affairs of the firm will be carried on at Southampton, Ont.

The R. L. Cushing Millwork Co., Ltd., Moose Jaw, Sask., have added a lumber yard to their premises and are now retailing lumber. A shavings exhaust system has also been installed in their plant, this comprising a 50-in. fan manufactured by the Canadian Blower & Forge Co., Ltd., of Kitchener, Ont.

The Doherty Piano Company, at Clinton, Ont., have made a change in their power equipment. In future they will run their machinery by electric power, supplied by the local Hydro commission, leaving the steam plant for dry kilns and reserve power. This industry is one of the mainstays of Clinton.

Wood Hydraulic Hoist & Body Co. Ltd., Windsor Ont., have been granted a federal charter to take over the business known as Wood Hydraulic Hoist & Body Co. and to manufacture and market all kinds of wooden boats. Two of the incorporators are G. A. Wood, of Algonac, Mich., and L. S. Wood, of Detroit.

The Montreal Harbor Commissioners recently saved $68,-750 by the use of the Panama Canal. Two shipments of lumber, aggregating 5,000,000 feet of Douglas fir, were taken half way around the world for $16 a thousand feet board measure, while the Canadian Railway rate at present is about $29.75 per thousand feet.

Mr. W. H. Slight, Stayner, Ont., well-known to the lumber trade, has recently purchased the interests of Messrs. Robinson & Dobson, consisting of a retail lumber yard and planing mill. He will continue in the business and expects to bring the plant thoroughly up-to-date for the manufacture of sash, flooring, moulding, etc.

Jos. Carr has recently started a planing mill and lumber

Uniform Lumber Means Greatest Satisfaction To The User!

You no doubt have experienced the expense, loss of time, and loss of materials, caused by the use of improperly cured, wrongly graded, and carelessly handled hardwood.

Kraetzer-Cured Lumber is absolutely uniform in quality, properly graded, and every board plainly marked, showing the grade. To show our faith in Kraetzer-Cured products, every board is stamped with our brand.

THE KRAETZER-CURED LUMBER CO.

Because of our unusual facilities we control the lumber from the virgin growth to the time it is loaded on the cars and shipped to you.

When you have once used Kraetzer-Cured Lumber you will not be satisfied with the ordinary kind. Read the eight important reasons why Kraetzer-Cured Gum is used by thousands with such satisfactory results. It will give the same results to you.

Kraetzer-Cured Lumber is of the very best quality, carefully handled by all departments. Every step in this process is taken with the idea of producing uniform high grade hardwood that will give maximum service in your hands.

In addition to Kraetzer-Cured Gum, we can furnish Oak, Ash and other Southern Hardwoods.

The Kraetzer-Cured Lumber Co.

GENERAL OFFICE: GREENWOOD, MISS.

Band Mills: Greenwood, Miss., Moorehead, Miss. Leflore, Miss.

You Should Use KRAETZER-CURED GUMWOOD *Because:-*

1. It is STRAIGHT and FLAT, free from the warp and twist usually encountered in untreated stock.
2. It is BRIGHT and will satisfactorily take any finish.
3. It is free from dote or rot—the sap and gums are eliminated by the steaming process, and fermentation and decomposition are thus prevented.
4. Through the elimination of stain and decomposition, it possesses greater strength and longer life.
5. It contains only atmospheric moisture, enabling it to be used for many purposes without kiln drying.
6. When kiln drying is necessary, this can be done in much less time and with more satisfactory results.
7. It is uniform and dependable. One car like another, grade and measurement what it should be—no time wasted in reporting complaints or shortages, no delays or interference with factory schedules because of holding lumber for adjustments.
8. It is the most economical lumber available. It will satisfactorily answer any requirements expected of materially higher priced woods. Join our little army of satisfied users, and just as peace is about to supplant war, let peace of mind take the place of the warfare and worries that usually beset the user of lumber.

We're proud of this product —that's why.

yard, known as the "Bee Hive Planing Mill," at Alliston, Ont. Mr. Carr will carry everything required for the building trade and intends to install additional machinery and extend his premises as soon as circumstances permit. At present he reports business very good.

Montreal Furniture Manufacturing, Ltd., Pointe Aux Trembles, Que., is a new concern with provincial charter to manufacture and sell all kinds of furniture, musical instruments, toys and other wood products. Capital $49,000. Two of the incorporators are C. G. St. Jean and J. V. Gervais, furniture dealers, both of Montreal.

The Renfrew Planing Mill Co., of Renfrew, Ont., are installing a flooring machine and a Sidman class A, progressive type, lumber curing kiln to manufacture a high grade of birch and maple flooring. They are starting off with a capacity of 10 M ft. per day, but expect in a very short time to increase this to 30 M ft. per day.

The Wilson factory at South Bay, N. B., has been operated steadily through the summer and will continue through the winter as usual. Alex. Wilson is the managing director of this industry.

The Blackmore-Hamilton Furniture Co. Ltd., Listowel, Ont., is a new firm recently incorporated to manufacture all kinds of furniture. The personnel of the new concern is president and general manager, N. Blackmore; vice-president, H. Hamilton; secretary-treasurer, R. A. Treleaven, The Board of Directors consists of the above gentlemen and Messrs. T. Burnett, J. H. Blackmore and L. Pfeffer, of Listowel. and N. Bonderick, of Milverton.

A large hardwood deal was recently completed when the E. L. Bruce Co., of Memphis and Little Rock. Tenn., U. S. A. and John Ransom Co., of Nashville, Tenn., took over the plant, stock and good will of the Nashville Hardwood Flooring Co. Change of ownership will not alter the management of the Nashville Hardwood Flooring Co., which has an authorized capital of $1,000,000. It is reported that the Bruce interests own a majority of the stock.

The Stratford Mfg. Co., Stratford, Ont., manufacturers of all kinds of wooden novelties and furniture, do a large export business with South Africa. Mr. Chas A. Moore, president and manager of this company had an interesting experience in Chicago recently in this connection. He was attending an illustrated travel talk on South Africa and was surprised and delighted to see park seats and lawn chairs made by his company in two of of the views.

George W. O'Neill, president and manager of the Risteen Co., Limited, Fredericton, N. B., dropped dead recently at his home in that city. Mr. O'Neill was born in Fredericton 67 years ago and for the past 45 years had been engaged with the Risteen woodworking factory, devoting his attention to the practical work of manufacturing until 21 years ago when he was appointed manager of the plant. Later he was elected president and managing-director. He is survived by his widow, two sons and two daughters.

The Western Manufacturing Co., Ltd., Regina, Sask., have been quite busy of late. They have just been awarded the contract for the seating accommodation and the main altar for the R.C. church at Ponteix; also the seating accommodation for the Masonic Hall at Shaunavon, Sask. They have also completed a contract for the interior trim, sash, doors, frames and stained glass windows for the R.C. church at Rosenheim, Alta. Another contract which has just been completed calls for all exterior frames and trim, all office fittings and seating accommodation, screens, and counters for the dining hall of the new C.P.R. station at Moose Jaw. The frames and trim for the C.P.R. divisional offices at Moose Jaw comprised another contract.

M. M. Wall, secretary and treasurer of the Buffalo Hardwood Lumber Co., Seneca St., Buffalo, N. Y., is associated with a syndicate in the holding of a fine tract of timber in the interior of B. C., about 400 miles east of Vancouver, which they purchased 12 years ago. Mr. Wall announces that this tract of 17,700 acres is about to be opened up and placed on the market. A recent cruise estimated the stand as over 250,000,000 feet of which about 150,000,000 was red cedar and 80,000,000 hemlock and larch. White pine, fir and spruce making up the total.

The Preston Woodworking Machinery Company, Limited, propose next spring to complete an addition of 100 feet square which were started a few years ago, provided that business continues good. This year they have added to their equipment a Bullard 36" vertical boring mill and a 36" Stirk planer. The company state that they are gradually developing their line of ball-bearing machinery. The machines are not altogether new, but are elaborations of the line they already make, so that they are able to offer their customers increased production and quality.

The Regina Sash & Door Co., Ltd., Regina, Sask., have recently erected a new warehouse and office at the corner of Athol St. and Twelfth Ave. This building is of solid brick, one storey high, and measures 100 x 60 ft. It is the first unit of a new plant that is planned to be the future headquarters of the company. The most modern equipment will eventually be installed in the new plant in addition to the present machinery, to take care of the firm's rapidly growing business. The present plant is situated on Angus St. and it is expected that the new premises will be occupied at an early date.

The W. E. Phillips Company, Limited, are now operating their new plant in Oshawa, with a staff of about fifty men. The volume business is satisfactory, being if anything in excess of capacity of the plant. Directors of the company are R. S. McLaughlin, president of General Motors of Canada, Limited, and W. E. Phillips. W. C. Phillips is associated with the company as is in general charge of sales. The plant contains approximately 30,000 ft. of floor space and product covers full range of picture mouldings, picture frames, advertising frames, framed mirrors, small novelties and hand-carved photo frames, etc. They also make a certain quantity of hardwood flooring and interior trim and are now completing installation of a glass department where they will bevel and silver their own mirrors.

The Creighton Woodworking Co., of London, Ont., has had a busy season and reports that the outlook is promising. Early in the year they extended their mill and reorganized their staff and they have now one of the best equipments in Western Ontario and are handling an ever-increasing volume of trade. Joseph Creighton, who is a successful cabinet maker with a long experience in millwork, is handling the shop end and W. H. Hawkins, who is widely known as an architect, is in charge of the outside work, contracting and service departments. The Creighton Woodwork Co. during the past season built eight houses of various designs and one church are at present well on the way with the construction of the new factory of the London Shippers' Containers Corporation. While there may be some lull in operation during the winter months, the Creighton Woodwork Co. are convinced that next spring will witness a revival of activity and they already have several contracts on hand. The company, whose plant is located at 701-709 Central Ave. East, London, specialize in store fronts, office and store interiors, partitions, fittings, shelving, cupboards, etc.

Moscow in Throes of Building Boom

Moscow to-day is passing through a building boom more active than anything of the kind the white-walled city has experienced in several generations.

Real estate improvement has been virtually at a standstill since early in the world war, and after the revolution, which eventually brought the seat of government back to the ancient capital, Moscow became one of the most crowded cities on the face of the earth.

This fall, however, under the Soviet's new economic policy, which permits private enterprise, including leases on property and buildings for 49 years, the rush to gain concessions by local investors began, with German, French and other foreigners also clamoring for privileges. The Government itself also has improved many buildings.

Hundreds of business houses, as well as fine old homes, were so badly damaged during the revolution that it was necessary to rebuild them. Walls of scores of other buildings, ruined by fire, are still standing in various parts of the city, but provision has been made for remodeling most of these next sprng.

Store space is in great demand, due to the stimulus given by the resumption of free trade, and numerous one-storey affairs have been put up in the shopping districts. They resemble the stores erected in a boom town in Canada or the U.S. Small wooden shacks for the retail selling of books, fruit, clothing and various necessities, have been built temporarily here and there throughout the city, but these will be pushed aside with the resumption of trade through the ordinary channels.

Entire blocks have been cleared for apartment houses, with shop space on the ground floor, and thousands of men and women—usually more women than men—have been employed in this work, carried on with great speed to get as much done as possible before the cold weather begins, when all outdoor tasks of this kind must cease until spring.

To Electrify 30-Mile Section of Vera Crux-Mexico Railway

Contract for the electrification of 30 miles of track on the Mexican Ry. Co. Ltd., between Orizaba and Esperanza on the main line from Mexico City to Vera Crux has been announced by the International General Electric Co. The project calls for the expenditure of between $2,000,000 and $2,500,000 and will be financed through London.

The system will be operated by 3,000-volt direct current which will be supplied by the Pueblo Tramway, Light and Power Co. from hydro-electric plant about five miles from Orizaba. The present contract includes ten 150-ton locomotives, equipment for one sub-station, overhead conductors and accessories. The ruling grade on the electrified section will be 4.7 per cent

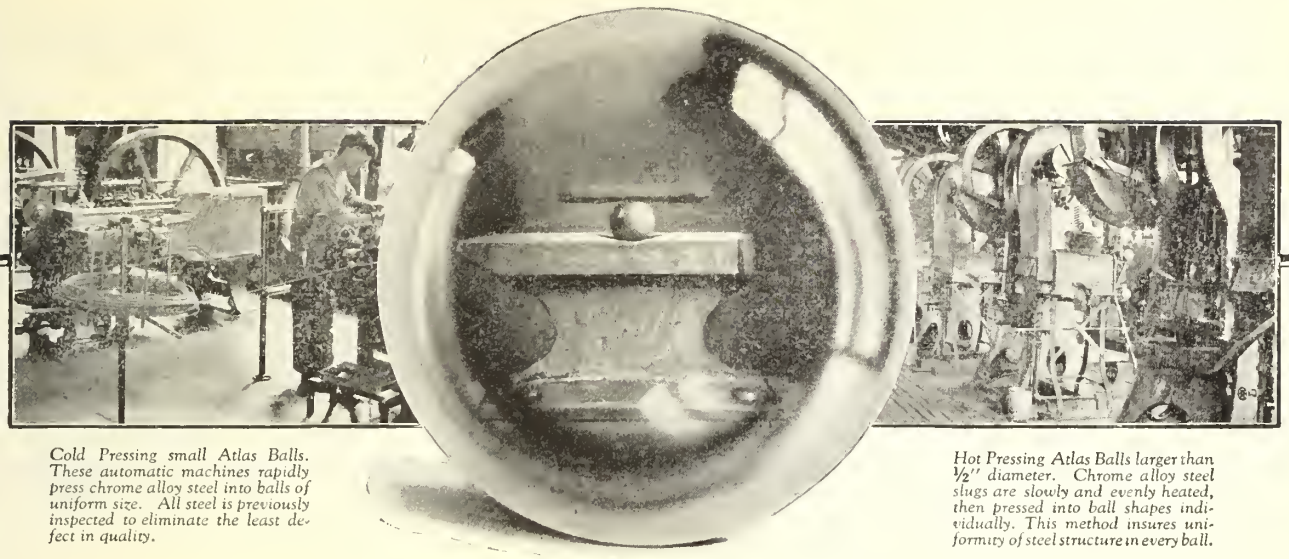
FRUIT PACKAGE MACHINERY
St. Joseph Iron Works, St. Joseph, Mich.



Cold Pressing small Atlas Balls. These automatic machines rapidly press chrome alloy steel into balls of uniform size. All steel is previously inspected to eliminate the least defect in quality.

Hot Pressing Atlas Balls larger than ½" diameter. Chrome alloy steel slugs are slowly and evenly heated, then pressed into ball shapes individually. This method insures uniformity of steel structure in every ball.

12 Tons of Crushing Weight Failed to Fracture This Ball

This mighty blow struck an ordinary half-inch Atlas Steel Ball — and the only happening of consequence was the sinking of the ball into the anvil top.

What *did not* happen to the ball bears mute evidence of the quality of the steel, and its heat treatment.

Exceedingly hard, tough and durable, the chrome alloy steel used in Atlas Balls affords remarkable resistance to the severest blow, shock, or pressure which commercial usage may apply.

Every ½" Atlas O. K. Ball will withstand over 12 tons pressure before fracturing—1" ball approximately 43 tons —1½" balls 70 tons. These are loads far in excess of those met in actual service.

For years Atlas Balls have had the quality approval of the bearing industry and of industrial concerns which demand balls of extreme accuracy and strength.

GRAND RAPIDS

Carborundum Brand Garnet Paper and Cloth in the Woodworking Centers of America

GRAND RAPIDS!
In 1833 the site of an abandoned Indian village—in 1850 a chartered city—and now the greatest, high-grade furniture center of America.

Grand Rapids is a great proving ground for garnet paper and cloth. There they have some of the largest, some of the most noted producers of furniture in the whole, wide world. In these plants are men who are masters of their craft.

These are the men who realize the true value of good garnet paper and cloth.

And frankly, that is the reason why so many of them favor and use Carborundum Brand Garnet Products. You will find them in practically every Grand Rapids plant, big or little.

They have earned their way in Grand Rapids because, first of all they are coated with North River Garnet—there is none better.

Secondly, because they are made right—made to cut clean and to give a smooth, uniform finish and to give production, in keeping with economy.

You have only to try Carborundum Brand Garnet in rolls, belts or finishing sheets to know why they use it in Grand Rapids—and every other big woodworking center.

The Canadian Appraisal Co. Limited

The Pioneer Appraisal Organization of Canada

Established 1905

"An adjustment of fire insurance in accordance with existing values is a universal necessity. Many people who now believe that they are properly covered against the fire risk are, in reality, inadequately covered. Morever, realization of these facts is by no means general."

The Chronicle

Over 85% of the appraisals made during the past fifteen years of Canadian manufacturing and industrial properties have been carried out by us, aggregating some 5.000. properties, and include over 250 lumber and woodworking plants.

Morgan No. 6 Nailing Machine

MORGAN
NAILING MACHINES

Used in Nailing Wooden Toys

Many manufacturers of American Wooden Toys use our machines for driving 5/8" to 1 1/8" nails. Machines are adjustable in operation and can be adapted to any kind of nailing work.

If you are driving nails by hand, in making boxes, crates, toys, any woodenware articles, figure the cost. It is expensive.

Then send us samples of your work. Get an estimate of the cost of nailing on a Morgan Nailing Machine. Compare the figures. We'll leave the rest to your judgment.

Send us your nailing problems. We shall be pleased to give them our careful consideration and advise you regarding equipment for handling them. We invite your inquiry.

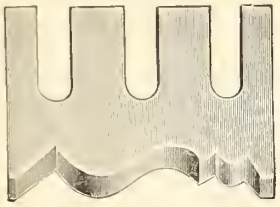
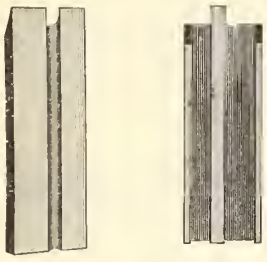
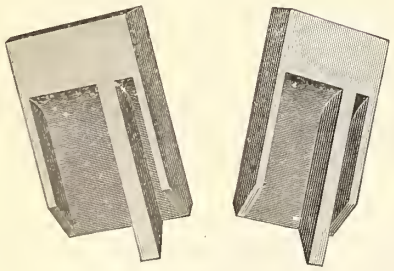
SIMONDS
Machine Knives





Woodworking shops, the machines of which are equipped with Simonds Knives are getting greater production and longer knife service. The high-grade steel of which Simonds Knives are made is tempered by a scientific method to hold its cutting edge longer and withstand wear.



Every kind of machine knife, as well as Saws which are required in the woodworking industry are produced in one of the five Simonds factories.

When you require knives send us your inquiries.

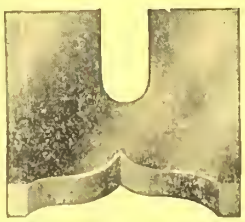
ATKINS

STERLING QUALITY

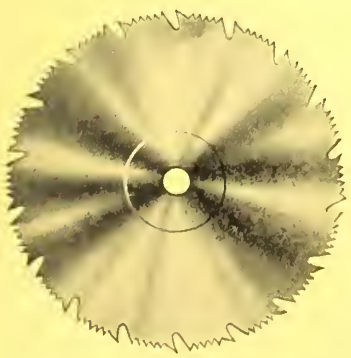
SAWS and KNIVES ECONOMIZE



ARE your saws and knives wasting your lumber? If so, why not turn that waste into a profit by installing

Atkins Sterling Quality Saws

and Machine Knives



Some of the largest woodworking mills in the country are using Atkins Saws exclusively, because they increase production, stop waste and make a name for themselves wherever they go.

Write to-day for our Knife Booklet "C.W." and Pattern Template Paper.

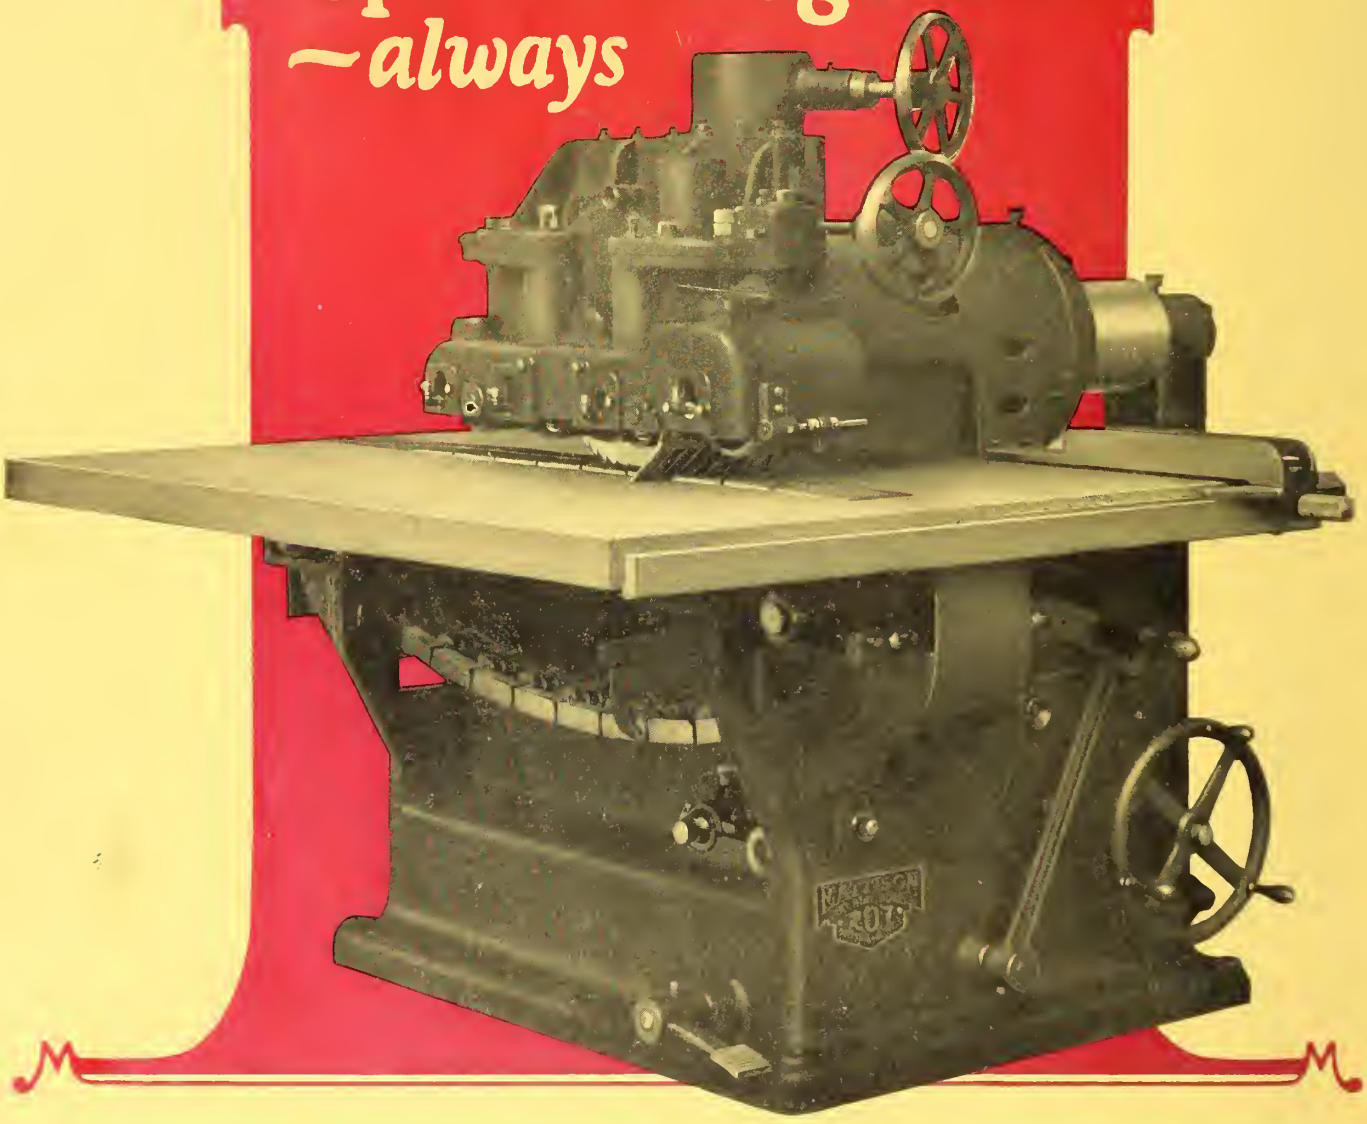
Rips in a Straight Line —always



The Ball Bearing Mattison Ripper

Further refinement in the design and construction of the Mattison Chain Feed Rip Saw greatly adds to its utility.

High-garde ball bearings, both for the saw arbor and the feed rolls, overcome friction and vibration, and assure a free-running saw which permanently remains in perfect alignment.

Wherever there is the slightest chance for wear, throughout the feed-works, the traveling chain and elsewhere, this machine is provided with simple, put positive, take-up devices.

Being able to compensate for wear is one of the reasons why the Mattison Ripper can be absolutely depended upon for accurate, straight-line ripping through years and years of hard service.

Our design provides for a compact built-in motor drive. The motor does not overhang, but is housed within the column which supports the feed-works.

Competitive tests prove this New Mattison Ball Bearing Rip Saw superior in operating convenience, quality ripping and mechanical excellence.
